

NEW YORK STATE JOURNAL *of* MEDICINE

Editorial

Salutatory

Our publication herewith appears in its new form. The Society will hereafter publish its organ of expression. *Vous l'avez voulu*

We greet our new obligations with emotions of deep responsibility. Hoping truly to express the opinions of organized medicine in this state, our endeavors will be to so mold public opinion that it will better comprehend its own interests in medical matters. For if it is true that the society which medicine serves usually molds the form which the practice of medicine takes, so it must follow that society itself needs authoritative opinion and advice before making vital decisions on the manner and the way it wants medical care delivered to it. We represent neither the methods, nor hold to the concepts of a trade union, nor of a guild. While it is axiomatic that the doctor must live, and from the exercise of those privileges which the practice of medicine imposes, he must maintain social and economic standards equal to those of the majority of the people he serves, yet the doctor's personal economic status is not our first and paramount concern. The public welfare is our primary concern.

Our endeavor will be that these, our pages, shall carry the newly discovered, the freshly devised, and the clinically proved advances in medicine. We envisage that our pages may become an open forum where differing viewpoints will be presented, not so much with the heat of debate as with the illuminating suffusion of light from the scholar's lamp. Constructive criticism is solicited. We desire nothing so much, in this our work, as that our readers shall take us into their confidence and write us that which we shall want to publish. No topic is tabooed nor do we espouse any partisanship.

We bespeak indulgence during our formative stage. We will grow, with your help, into a journal of opinion not alone on matters of scientific import, but also on the casual happenings in the environments of medical practice.

To the professions allied to medicine we offer our pages too. For what vitally affects them concerns us also—all to the end that the

people of our state will be better served, have better doctors, finer hospitals, the best possible dental and nursing care, and they—our people—enjoy the pursuit of happiness in healthier surroundings and in fine, robust health

Many-Sided Truth

“The British Experience” as described by Douglass W Orr and Jean Walker Orr in their book, *Health Insurance with Medical Care*, is at marked variance with the experience of A G P , a British physician, as recorded in a volume entitled *This Panel Business* A G P , although strongly in favor of the principle of National Health Insurance, sees many serious flaws in its operation The Orrs, who were sent to Great Britain by a group in favor of compulsory insurance here, find general satisfaction with this system among all classes of the population, including the medical profession Truth is indeed in the eye of the beholder!

The Orrs find little to criticize in the quality of service rendered under National Health Insurance They discount the charge that examinations are hurried and superficial and stress the advantage of early recourse to medical care To A G P any such advantage is lost because of the fact that “panel practice as it is known today is medical practice in a desperate hurry” In a typical morning’s panel work, he complains, only about four minutes can be allotted to each patient often there is not even time for the latter to undress It is a generally admitted fact that the preventive potentialities attributed to National Health Insurance have so far failed to materialize

The Orrs refer frequently to the financial benefits to the medical profession from National Health Insurance One or two doctors whom they cite earn \$9,000 and \$12,000 a year, live on small estates, and have two cars A maximum panel of 2,500 would bring in approximately \$5,000 a year, leaving \$4,000 to \$8,000 more to be earned by these fortunate physicians in private practice And yet these men, with 2,500 panel patients and an additional private practice bringing in \$4,000 to \$8,000 are not too rushed to give careful service, if the Orrs’ observations are to be accepted without question

Fortunately or unfortunately, their cases are hardly typical, according to A G P A panel with the theoretical average of 976 insured persons brings in less than \$2,000 a year, out of which the practitioner must pay his rent and all other expenses He is, of course, permitted to treat private patients too—if he can get any—but it must be born in mind that three-eighths of England’s population is insured The dependents of this group constitute a slightly

larger fraction, many if not most of whom apply to public agencies for medical care. About 32 per cent of the population is entirely on relief, leaving a very small class from which additional private practice can be obtained.

If National Health Insurance were extended to dependents, as the Orrs say most people desire, the additional capitation fee would be very low. A G P estimates that coverage of the entire population would yield physicians an average net income of no more than \$1,775—hardly a fair return on the long and costly preparation for medical practice and the hard work and heavy responsibility it imposes.

The Orrs accept the viewpoint that National Health Insurance has improved the lot of labor in Great Britain but they cite no concrete supporting proofs. Perhaps the reason for this is, as A G P asserts, that there are no convincing statistics to show that twenty-five years of compulsory insurance has improved the health of British workers.

Doctors Agree

The recent meeting of the New York State Temporary Commission to Formulate a Health Program disclosed almost complete agreement among the medical men who testified. Both public health officers and representatives of organized medicine endorsed voluntary health insurance as a means of supplying low-cost medical care to the medically indigent. Both public health officers and the spokesmen of private practice agreed that compulsory insurance is unnecessary and would jeopardize the standards of medical care.

The arguments of organized medicine against obligatory prepayment are too well known to the profession to require repetition here. It is significant to find a similar point of view in public health officers in close daily contact with the needs of the poor and known for their progressivism.

Dr S S Goldwater, Commissioner of Hospitals of the City of New York, called attention to a fact which is frequently ignored by advocates of compulsory sickness insurance. Speaking for his own community, he asserted that medical service is "more readily accessible to the underprivileged than proper shelter, health-sustaining food, suitable clothing and facilities for recreation." This is true almost everywhere. "For the low-income, not quite indigent group unrealized benefits are available through voluntary insurance which should be developed further. Independent self-help probably suits the American character better than dependence on government aid."

Similarly State Health Commissioner Edward F Godfrey agreed that "some kind of insurance is desirable" but there is no necessity for compulsory insurance. It cannot be overemphasized that these men know both the needs of the poor and the available machinery to supply them. They do not speak from sentiment or theory but from knowledge.

In view of the unanimity of opinion among responsible public health officers and the representatives of private practice, the State Temporary Commission must hesitate to throw its influence behind compulsory sickness insurance. This system is like the Old Man of the Sea. Once it gets a hold on the taxpayer, it bears down on him even more heavily and is almost impossible to dislodge. The benefits, European experience has shown, are incommensurate with the heavy burden.

The Bronx County Medical Society's Twenty-Fifth Anniversary A Tribute to Dr. Nathan B. Van Etten

The Medical Society of the Bronx, on January 7, will celebrate its twenty-fifth anniversary with a dinner at the Waldorf-Astoria. The event takes the form of a tribute of esteem to Dr. Nathan B. Van Etten—the outstanding leader in organized medicine of that county.

Dr. Van Etten was the first president of the newly organized Medical Society of the Bronx, when it separated from the Medical Society of the County of New York twenty-five years ago and became a component unit of the State Society. Since that time Dr. Van Etten has continuously been a leader in organized medicine. As President of the State Society, as editor of this JOURNAL, and more recently, as Speaker of the House of Delegates of the A M A, his face and figure are familiar to us all. His wisdom in council, his poise and philosophic calm in debate, as well as his tolerance for the inferior intellect and man of smaller stature, brought him respect from everyone and love from many.

During his whole career, he has practiced medicine in the high traditions of his calling, and in his public appearances and addresses he consistently championed the practicing physician and the important rôle he plays in the health of the community.

To the many voices which will bring deserved tributes to Dr. Van Etten, we would add ours. We delight to say to sentient ears the well merited word of praise, admiration, and commendation. In the years which are still before him, we look to this wise counselor for such guidance as a wisdom born of years of public officialdom and private medical practice has endowed him. Whether he

holds public office or not, Dr Van Etten remains a valuable force, and a potent factor in our Society. Congratulations!

A Tribute to Dr Ellsworth Eliot, Jr

The painter Sargent, hearing a lady commenting on one of his canvasses and doubting the authenticity of the colors with which he had painted some cows, facetiously replied to her remark that she had never seen cows of such color, "Well, wouldn't you like to have seen some!" In life things often happen which fulfill so useful and important a rôle that had they not happened they surely would have had to be invented. This is also true in medicine. The evolution of progress creates so pressing a need that, if authoritative sources do not respond to the urge, some one arises and creates the very situation which supplies the needs.

We are prompted to these observations because of a small book which recently came to hand from the pen of Dr Howard Fox, now president of the Medical Society of the County of New York, a distinguished son of a former president of our State Society. This book, entitled *Eliot's Quiz*, is a tribute to an outstanding teacher of medicine in New York—Dr Ellsworth Eliot, Jr.

Medicine was not taught in Eliot's day. Yet the necessity for teaching medicine was being keenly felt. Dr Eliot characterizes the teaching of his day as both elementary and rudimentary. The instruction was given chiefly by didactic lectures and weekly clinics. There were neither conferences nor obligatory recitations. At the college clinics the student actually was little more than a spectator. Attendance at clinics and lectures was voluntary.

Strange as it may seem, it was not the knowledge of its shortcomings on the part of the college authorities, nor the desire to produce better doctors which became the inciting motive which wrought changes in the medical educational system, but rather the urge of the student body to supplement the paucity of recitations and classroom instruction that resulted in the establishment of the Quiz Classes. In the student body those whose ambitions led them particularly to seek positions on the interne staffs of great hospitals were the real urge which not only made necessary this supplemental instruction, but was the most important factor in elevating the standards of medical education in the last generation.

There is an old Hebraic legend which tells that King Solomon, desiring to know the one most responsible for the building of the Temple, asked claimants for this distinction to state the basis of their claims when applying for his regal honors. Masons, carpenters, decorators, and artisans of all types and descriptions applied, and

each stressed the importance of his own particular work in the building of the Temple. A hitherto inconspicuous man also pressed his claim. He demanded the supreme honor, because he said that he made the *tools* with which all the others worked. Without tools their work would have been impossible. Solomon, in his wisdom, granted this man the much desired honors.

Dr. Eliot made the medical tools with which the current generation of physicians works. He made teachers of medicine of the current generation. Quietly and inconspicuously he worked. He attracted talent, taught it, guided it, and prepared it to teach others in turn. Look at the list. Six deans of medical schools, 112 professorships in medicine, 111 instructors, 100 visiting physicians, and 104 visiting surgeons, forty-four visiting specialists, and 161 consultants to medical institutions. This, besides two Directors of the New York Academy of Medicine, in addition to other important positions his students hold! One cannot scan such a list without according high honor to this teacher of teachers. This is a man who truly left his imprint on American Medicine. We are proud of the record, and hope that Dr. Eliot may continue to enjoy the evening of life in quiet contemplation of his fine efforts and enjoy watching the spread of his influence no less than the continued love and admiration of his students.

Modern Antiluetic Therapy

The problem of syphilis control presents many ramifications. By no means has a successful solution for its complete eradication been put into effect despite state acceptance of the responsibility of guarding its citizens against the disease. Prophylaxis, and by that we mean prophylaxis on the part of the individual, has not been taught as intensively as it should be. Stress has been laid more on the early recognition of syphilis and the adequate treatment of the malady, and, until such time as preventive measures will have become common knowledge, these are our only potent weapons to combat its spread, reduce its incidence, and decrease organic lesions.

With the exception of those specially skilled in the management of syphilis, the treatment ordinarily administered is more or less haphazard in the hands of the average practitioner. True, antiluetic remedies are given, according to some formula or regime, and the patient's serology is checked at intervals, but rarely is treatment for a patient individualized so that the maximum benefit can be obtained. The series of articles by Dr. A. Benson Cannon, the first of which appears in this issue, is therefore a timely contribution. It represents a synopsis of the methods he has found from his own ex-

perience to be the most effective in the treatment of syphilis, and which were developed in the Department of Dermatology of the Vanderbilt Clinic

From the numerous factors which he considers, we call attention to but a few. Continuous treatment is far superior to intermittent treatment, since it keeps the patient at all times under the influence of an antiluetic drug. "Of the arsphenamine series, the one which has maintained its superiority so far against all new comers is Old Arsphenamine, or simply arsphenamine, originally elaborated by Ehrlich as 'Salvarsan' or '606'." This drug, despite former prejudice against its use because of pain and local necrosis, heals lesions quicker and produces a negative Wassermann in a shorter time. A safe, simple technic for its use is described.

Every phase of the subject is thoroughly covered, and the individual variations indicated for the therapy of syphilis in pregnancy, aortitis, nephritis, anemia, and other conditions are detailed. Treatment of early and late neurosyphilis, and the technic of intraspinal and malarial therapy are described concisely. Furthermore, since most reactions to arsphenamine are preventable, Cannon furnishes the data which will enable one to avoid them and indicates the 'warning symptoms' to be looked for.

This series of articles by Cannon furnishes a compendium of the therapy of syphilis which will serve the physician as a reference and guide. It lacks nothing in the way of completeness, from the minutest details of technic to the answer to what one can expect from treatment.

Significance of Hoarseness

We have previously commented in this JOURNAL upon the importance of hoarseness as a symptom in the early detection of laryngeal carcinoma. Its significance, however, is far wider—in that often it is the sole precursory evidence of other diseases which, when diagnosed quickly, respond readily to measures adequately instituted. Mr. Victor E. Negus, in his address before our State Society in May, 1938, the text of which is published on page 6, has clearly defined the various causes of hoarseness at different ages.

In children, acute inflammations are largely responsible for the appearance of this symptom. Diphtheria, of course, is the most dangerous of the etiologic factors, but vegetable foreign bodies and papillomata may in addition cause stridor and dyspnea which may require operative intervention. In the young adult, the hoarseness of simple chronic laryngitis is usually the result of faulty use of the voice, or a purulent focus in the nasopharynx. One must, how-

ever, be extremely suspicious of early laryngeal tuberculosis in every young adult whose voice remains persistently husky. Timely recognition of the laryngeal lesion will lead to therapeutic means for checking the disease. Hoarseness in elderly people, men particularly, should be regarded with utmost gravity. "An elderly man with gradually increasing hoarseness must be suspected of having a carcinoma of the vocal cord unless it can be proved otherwise."

Negus emphasizes that a complete examination by a skilled laryngologist should be performed in every instance where a person is continuously hoarse for more than three weeks. By close supervision of the hoarse patient, the general practitioner will be able to arrive at an early diagnosis of many serious ailments before they have passed beyond the curative stage.

Current Comment

"The power to tax plus the power to regulate may destroy the freedom of public opinion and make a dictatorship inevitable, because it may be necessary for Government to take over all agencies of public opinion in order to maintain its power to tax and to regulate." Carl W. Ackerman, Columbia University Dean, at the National Municipal League's conference on government in Baltimore, quoted in part by the *New York Sun* of Dec 3, 1938.

"The almost obstreperously obvious lesson of current international history is that *the world belongs to the man who has a program*." To be found in the Dec, 1938, issue of the *Westchester Medical Bulletin*.

"The medical profession is the most powerful and coherent of any of the professional groups. With its definite professional preparation and objectives, the considerable background of general education that is now prescribed and the code that it professes, it comes nearer meeting the technical definition of a profession than any other major profession." Excerpts from an address by Guy Stanton Ford, Ph D., Dean of Uni-

versity of Minnesota Graduate School.

"Families living in small midwestern cities 'are more likely to economize by not seeing the dentist, the oculist, or even the doctor than by not buying supplies for the family medicine chest, when funds run low'.

"This is the announced conclusion of a survey made under the direction of Dr. Louise Stanley, chief of the Bureau of Home Economics of the Department of Agriculture.

"The survey was made of 3,118 native nonrelief families living in Lincoln, Ill., Boone, Iowa, Columbia and Moberly, Mo., Mount Vernon and New Philadelphia, Ohio, and Beaver Dam, Wis.

"Not until the family income reached the \$500 per year level did the reports show as many as half the families consulting a physician. Incomes were nearly three times this (\$1,250 to \$1,499) before half the families spent money for dentists." Interesting facts to be found in the St. Louis County (Kan.) Medical Society *Bulletin* for Dec 9, 1938.

"The physician is the flower of our civilization" claimed Robert Louis Stevenson, and we feel it fitting to quote him

THE SIGNIFICANCE OF HOARSENESS

VICTOR E. NRGUS M.S., F.R.C.S., London, England

Surgeon for Diseases of the Throat and Ear King's College Hospital

HOARSENESS is so common a symptom of many diseases of the larynx that its study entails an examination of practically all the pathological conditions affecting the organ. The recognition of the cause is of great importance, and a full knowledge of the subject is well worth the study of all practitioners. In many cases hoarseness is merely an inconvenience of no great import, but it may be an early symptom of progressive disease which will kill the patient if not arrested.

The definition of hoarseness is a pathological alteration of the sound produced at the larynx. This sound consists of a fundamental and overtones. The word does not refer to alterations in the resonating cavities, with changes in the quality or character of the voice, such as those peculiarities of nasal tone due to obstruction of the nasal fossae, or to defective closure of the nasopharyngeal sphincter.

Nor does it refer to disorders of articulation, such as slurring, stuttering, and stammering, which are due to incoordination of the muscles concerned in respiration, phonation, or articulation, with no discoverable organic changes.

It will simplify the discussion if the disorders occurring at different ages are considered separately, the incidence of disease varies considerably according to the time of life.

Hoarseness in Children

An important cause of hoarseness in children is *diphtheria*, the first symptom of which is, generally, sore throat. Local inspection and bacteriological examination establish the diagnosis. Associated dyspnea, pyrexia, and severe illness would afford further evidence.

Simple acute laryngitis in children is of sudden onset and usually, but not always, associated with pyrexia and signs of inflammation in the nose and pharynx, there is an absence of true membranous deposits and Kleb's Loeffler bacilli. Dyspnea is a possible symptom, but not so commonly as in marked diphtheric types of infection. The significance of increasing hoarseness in such cases is important, as it gives warning that obstruction may follow, with the necessity for bronchoscopic aspiration, intubation, or tracheotomy.

A third type of acute inflammation causing sudden change in the voice follows the inhalation of a *vegetable foreign body*, with consequent acute tracheobronchitis and inflammatory swelling below and around the glottis.

Gradually increasing hoarseness, unassociated with fever, is not common in children, but when present it has two main causes. One is chronic laryngitis of simple or atrophic type, and the other is the presence of papillomata.

Chronic laryngitis may be caused by misuse or overuse of the voice, it is frequently associated with nasal obstruction or with inflammatory changes in the nose, postnasal space, sinuses, or pharynx. There is no laryngeal obstruction. The most common cause in childhood is catarrhal infection of adenoids.

Papillomata, on the other hand, are purely local and produce stridor or dyspnea if at all large, sometimes sufficient to require tracheotomy. The results of this operation may perpetuate the symptom of hoarseness if the cannula has been inserted too near the cricoid cartilage, with production of *perichondritis* or *cicatricial stenosis*, or with *fixation of the arytenoid cartilages*. The cause of stenosis

is readily ascertainable from the history, but the treatment is difficult

Laryngismus stridulus and *congenital laryngeal stridor* produce temporary changes in the voice, but are not likely to be confused with the conditions mentioned above

Hoarseness in Young Adults

Acute laryngitis, *diphtheria*, and *vegetable foreign bodies* affect others besides those of youthful years, but less frequently as regards the two latter complaints. Hoarseness, here again, may be due to *fixation of the cricoarytenoid joints*, following diphtheria or high tracheotomy, as in children. The majority of such cases are of long standing and their recognition is easy. Breaking of the voice in youths at puberty must be distinguished from vocal defects of pathological type.

Simple chronic laryngitis may cause a change of voice and is particularly liable to affect teachers, as at a younger age, some cause in the nose, sinuses, or throat will give a clue as to the diagnosis. Excessive smoking may be a cause of huskiness. Young women with soprano voices may develop *Singers' Nodes* on the vocal cords, or they may be due to small submucous hemorrhages resulting from faulty voice production. The node is readily seen but not so easily cured, an improved method of singing must be taught after the node has disappeared as a result of rest or operation.

A serious condition to be suspected in a young adult whose voice is husky is *laryngeal tuberculosis*. The pathological cause may be little more than weakness of the intrinsic laryngeal muscles, secondary to general asthemia, or to a mild catarrhal inflammation of the cords at their posterior extremities. When advanced, there may be tuberculous deposits in the interarytenoid region or infiltration and ulceration of the vocal cords. The significance of persistent hoarseness in such a case must not be overlooked, because of the gravity of the disease and the necessity of early and prolonged treatment, in fact, it is the habit in most sanatoria

to examine the larynx of all patients suffering from pulmonary tuberculosis. Early signs of disease may thus be discovered and checked, even before the patient has become aware of any obvious change in the voice.

The prognosis in a case of pulmonary tuberculosis is made considerably worse if the larynx is affected, a patient with affection of part of one lobe only, who would otherwise be classed in Group 1 is placed in Group 2 if laryngeal tuberculosis is discovered.

The treatment is affected by this complication and must be prolonged and thorough. Collapse of the lung by artificial pneumothorax gives good results. The prospect of cure of the larynx depends primarily on the progress of the pulmonary and general systemic condition. Rest of the vocal cords is essential if the tuberculous deposits are to heal. It is important also to forbid use of the arms for such exercises as golf or digging in a garden, most actions which necessitate fixation of the chest during use of the pectoral muscles are accompanied by closure of the vocal cords.

Even when the laryngeal disease is healed the prognosis for the future is serious. Recurrent roughness or weakness of the voice must be taken as a danger signal and should direct attention, not only to the larynx but also to the lungs and the resistance generally.

If hoarseness is associated with dysphagia the outlook is gloomy, as there is then a probability of involvement of the aryepiglottic folds, possibly with ulceration, this points not only to widespread tuberculous infiltration, but also to the danger of lack of nourishment because of pain on swallowing.

Hoarseness in Adults

Inflammatory diseases, both acute and chronic, may occur at any age, and sufficient has been said already about those of simple and tuberculous type. Tobacco, alcohol, misuse, or overuse of the voice are important factors. *Syphilitic laryngitis* is, at the present day, rare in the south of England, in the course of the

year many patients with tuberculosis of the larynx are seen but few with syphilis, either of the tertiary or secondary type. A robust man is the most likely subject, and the voice is strong but rough, other signs of the disease may be found in the pharynx, while blood tests give confirmatory evidence. Syphilitic affections of the larynx are usually tertiary, while the pharynx is more often involved during the secondary stage. *Malignant neoplasms* are rare, except in elderly individuals, the subject will be dealt with in a separate section below. *Simple neoplasms* are uncommon but sometimes occur as fibromata, papillomata, or cysts. The only means of diagnosis is visual examination, followed if necessary by biopsy.

Neurological disorders appear in considerable variety, but not with frequency. *Bulbar palsy* is perhaps more often seen than are other types, but *syringomyelia*, *disseminated sclerosis*, *tubes*, and *general paralysis* may all appear. The changes of voice are due in part to affection of the intrinsic laryngeal musculature, but there generally are in addition characteristic disorders of articulation, caused by weakness or paralysis of the muscles of the pharynx, lips, and tongue. The voice in bulbar palsy has so peculiar a slurring quality that once heard it is not forgotten.

There may be associated symptoms of difficulty in swallowing, with collection of saliva in the pharynx, which makes the diagnosis easy. As well as these central diseases affecting the nucleus ambiguus there are many cases of hoarseness due to peripheral lesions of the recurrent laryngeal nerves. If one nerve is out of action, with paralysis of the intrinsic muscles on that side, the voice is husky, but there is no dyspnea, except on extreme exertion, unless there is some associated lesion in the thorax. Examination will reveal the immobile vocal cord either in the adducted or in the cadaveric position, search must then be made for a tumor at the base of the skull, a malignant growth in the esophagus, enlarged glands in the neck, or something in the mediastinum as the cause of pressure. If there is a large

mediastinal tumor or aneurysm there may be difficulty in breathing and often a brassy cough, dysphagia, also, may be present. Neuritis may cause the lesion and may follow diphtheria, influenza, or some other fevers, or may be due to metallic poisoning, as by lead.

It is possible for the recurrent nerve to be caught up in scar tissue after *thyroid operations*. If one cord only is affected the patient does not suffer any serious disability, but if both sides are paralyzed there is extreme dyspnea with stridor, requiring tracheotomy as an emergency measure. Luckily this accident is infrequent.

Hoarseness Affecting Women

In addition to the many causes mentioned as affecting young adults of both sexes, women are the subjects of certain other affections of the larynx. One of considerable importance is *functional aphonia*. It may give a breathy tone to the voice or may even make the patient completely voiceless. The reason for the upset is inability to bring the vocal cords together on attempted phonation, when air is expelled from the lungs it escapes through the partially or completely open glottis with the production of no more than a feeble whisper, accompanied by considerable air waste.

There is no difficulty in respiration, as the vocal cords can separate normally, and there is no inability to cough—a test of some value—or to close the larynx during swallowing. Laryngeal tuberculosis must be excluded, the remedy then consists in mild electrical stimulation combined with suggestion and reassurance. Occasionally the exact opposite is met with, the patient experiencing difficulty in speaking because of excessive closure of the glottis, the condition may well be described as hyperphonia.

Another complaint affecting women more frequently than men is postcricoid carcinoma. The neoplasm may start at the mouth of the esophagus and in time may spread up on the posterior surface of the larynx. Edematous swelling of the arytenoepiglottic folds is produced,

with some impairment of movement of the arytenoid cartilages. Defective movement of the vocal cords, together with associated inflammatory swelling in the posterior part of the larynx, causes hoarseness. This symptom is associated with difficulty in swallowing and sometimes with pain referred to the ear. The significance of hoarseness in such a case must not be overlooked, as on early diagnosis depends the possibility of cure, either by excision of the growth or by irradiation.

A precursor of this type of growth is chronic inflammation of the cricopharyngeal fold, sometimes known as *chronic hypo-pharyngitis*. This affection sometimes leads to changes in the voice, even when no malignant changes are visible.

Hoarseness Affecting Elderly Men

A condition of the utmost significance must now be considered and that is *intrinsic carcinoma of the larynx*. Men around sixty years of age are the chief victims, but others as young as forty-five or as old as eighty may be affected. It is of great importance to establish an early diagnosis, if cure is to be attained. The results of treatment of localized growths are so satisfactory as to reward to the full the practitioner who recognizes the disease before it has spread widely. An elderly man with gradually increasing hoarseness must be suspected of having a carcinoma of the vocal cord unless it can be proved otherwise. Skilled examination will establish a diagnosis. The cause of the vocal disorder may be simple laryngitis, in which case a cause may be present in the nose, sinuses, or pharynx, even if this is the case there may still be malignant changes commencing in the chronically inflamed mucosa. Treatment must be instituted to improve the inflammation in the nose and pharynx, and vocal rest, with avoidance of smoking, must be insisted upon for at least three weeks. If the inflammatory laryngeal changes disappear or improve considerably it will then be possible to say whether a neoplasm is present.

Greater difficulty is experienced when *hyperkeratosis* is present, as the chronic

thickening of the mucous membrane does not respond well to treatment. As with other types of chronic laryngitis, the patient must rest the voice, using only a gentle whisper or, better still, maintaining complete silence. He should be given small doses of potassium iodide and a nebulizer producing a fine cloud of mild sedative oils in a base of paraffin or benzoin. Failure to improve suggests the desirability of further investigation, if necessary by biopsy. It must always be in the forefront of the medical practitioner's mind that intrinsic carcinoma of the larynx commences on the anterior part of the vocal cord, while keratosis has a more diffuse distribution. The localized form of keratosis, known as *pachydermia laryngis*, is confined mainly to the region of the vocal processes of the arytenoid cartilages and is therefore generally distinguishable from the early stages of carcinoma. An extrinsic carcinoma of the larynx, involving the aryepiglottic fold or epiglottis, will cause hoarseness if it invades the laryngeal aperture, or causes secondary swelling. Associated symptoms of difficulty in swallowing and pain referred to the ear help to establish the diagnosis.

Conclusion

The object of this paper has been to give a general and necessarily superficial review of the conditions producing hoarseness and to stress the significance of the symptom, particularly as regards the possibility of early and therefore curable tuberculosis and malignant disease. It is the general practitioner's privilege and duty to save many lives by early recognition of these serious complaints in their early stages. No individual should be continuously hoarse for more than three weeks without obtaining the benefit of a skilled report on the condition of his larynx.

. . .

I am extremely grateful to Sir St. Clair Thomson for reading and correcting this paper and for offering many criticisms of great value.

THE RELATION OF DIABETES TO SURGERY

IRVIN ABELL, M D , Louisville, Ky

President American Medical Association

IT is well within the memory of many in this audience that the occurrence of a surgical lesion in a diabetic was regarded as heralding the approach of dissolution. At that time diabetics were regarded as extremely bad surgical risks, operations were undertaken mostly for emergencies, always with much trepidation and ended only too frequently in death from coma and acidosis. Today with the help of insulin and modern knowledge concerning perverted metabolism and the means for its correction not only emergency surgery but that looking toward repair and prophylaxis is done with reasonable assurance of success.

As a result of modern methods, more diabetics are reaching adult life and more advanced years and, being subject to the surgical conditions of the respective age levels, they show an increased percentage in surgical practice. In well-organized clinics with close co-operation between the medical and surgical staffs the mortality from operations on diabetics compares very favorably with that for similar lesions in corresponding age levels on non diabetics. That such has been made possible represents a triumph for modern medicine but its accomplishment necessitates meticulous care in carrying out the various details of treatment and in the exercise of medical and surgical judgment.

While diabetics can be prepared for surgical procedures certain factors combine to make them potentially poor surgical risks. These are an increased susceptibility to shock, intolerance to trauma, cardiorenal lesions, lessened recuperative and reparative powers, the ever present threat of acidosis, co-existent arteriosclerotic changes, depletion and dehydration from the effects of starvation, diarrhea, and vomiting, and the dis-

turbing effect upon metabolism exerted by fever and infection. In estimating the surgical risk of a patient with diabetes these problems must be borne in mind in addition to the immediate surgical condition presented and further consideration given to (1) complications, (2) hazards peculiar to the abnormal metabolism of diabetes, (3) the effects of insulin, and (4) the pathology associated with diabetes. In general, it is true that the higher the blood sugar, the graver the prognosis although the extent of hyperglycemia is not always an absolute index of the severity of the disease.

Routine urine examinations are usually relied upon to exclude diabetes before operations and while glycosuria is usually present in hyperglycemia exceptions are not infrequently noted in surgical cases. Certainly the correlation between the amount of sugar in the urine and in the blood is not a close one. Hypoglycemia may be noted in debilitated, emaciated patients and must needs be corrected before operation is undertaken. Acidosis greatly increases the risk to the surgical patient while emergency operations can and must be done in the presence of acidosis, operations of choice should be deferred until the urine is free of ketone bodies.

The hazards peculiar to the abnormal metabolism of the diabetic are to be found in the increased metabolism of hyperthyroidism, infection, and overfeeding and in the decreased metabolism of exhaustion from undernourishment. The more rapid and more recent the exhaustion, the graver the condition of the patient. The use of insulin plays an important part in estimating the danger to the patient and the suitability of the latter for operation. The common mode of

*Read at the Annual Meeting of the Medical Society of the State of New York New York City
May, 1938*

death of surgical diabetics before the introduction of insulin was acidosis or coma. Today this is rarely seen, the cause of death being directly attributable to the surgical lesion. Insulin prevents or cures acidosis and enables the patient to take a fuller diet, promoting increased resistance and favoring recovery.

The pathology associated with diabetes that is important from a surgical standpoint is to be found in the arteries of the extremities, particularly of the legs. The vast majority of diabetics coming to operation are above forty years of age with a high percentage of these between the ages of fifty and sixty, at which period of life arteriosclerosis is a common finding. In the nondiabetic the changes in the arteries of the extremities are largely found in the middle coat consisting of calcification with thickening of the intima and deposit of atheromatous material. In addition to this typical arteriosclerosis Warren and Smith have described another type of arterial lesion in the diabetic consisting of endothelial proliferation and fatty deposition in the intima. This type may develop fairly rapidly or may be present for long periods before gangrene supervenes. In the slowly developing cases of both types the best development of collateral circulation was found while in some cases of short duration advanced intimal change and absence of compensatory collateral circulation obtained. Diabetic gangrene is rare in the youthful patient, being most common after the age of fifty. Doubtless its frequency at and after this age is associated with the increased incidence of general arteriosclerosis at this age. The effect of chronic hyperglycemia and the disturbance in the metabolism of fats, particularly the results of long continued hypercholesterolemia, which is said to promote calcification and obliteration of the lumina of the vessels, are factors which are believed by many to be of great importance.

The preparation of diabetic patients for operation will vary with the absence or presence of infection in the lesion for the relief of which the operation is to be un-

dertaken. In the absence of infection the time element is not a factor, consequently the surgical procedure can be deferred until such time as the objectives of preparatory treatment are attained. These are, first, freedom from acidosis and glycosuria on a diet providing at least 15 calories per pound of body weight with or without the use of insulin and, second, the procurement of the most advantageous conditions for operation both as regards the nutrition of the patient and protection from infection. In the elective cases that permit of such preparation the results at the present time are uniformly satisfactory, the control of the diabetes allowing the case to pursue its ordinary surgical course. While the practice of starving patients before operation has largely been discarded, it certainly has no place in the preparation of the diabetic. Adequate reserve of glycogen, fluids, and salts are essential and these can be maintained only by proper nutrition, hence, feedings should be continued until a few hours before operation. In the cases in which insulin is employed in the preparatory treatment, it should be discontinued when the feedings are discontinued to give it after this time raises the danger of hypoglycemia and of increasing the susceptibility to shock.

In the presence of surgical emergencies nothing is to be gained by delay. In fact when these possess infection as a feature, delay may be actually harmful. Infection tends to increase the sugar content of the blood and to act as an inciting cause of acidosis and coma, furthermore it limits the efficacy of insulin, hence the necessity for its control or elimination without delay. After the administration subcutaneously of 20 to 30 units of insulin and of 1,000 cc. of saline solution intravenously the operative procedure is carried out, after which the further treatment of the diabetes is based on the blood and urine findings. The operation should be carried out as expeditiously as is consistent with thorough work, accurate hemostasis, and the minimizing of trauma. It is rarely necessary to give insulin during an operation. The dehydration resulting from

the acute illness should be combated by the administration of fluids, preferably saline, which may be started during the operation. The choice of supplying it subcutaneously or intravenously will be made upon the condition of the patient, particularly the cardiovascular system since it is advisable to avoid placing an undue strain on a weakened or damaged heart. While intravenous and subcutaneous administration of glucose is frequently necessary, oral feeding should be started as soon as the patient's condition allows since glucose, given parenterally, escapes the glycogen barrier of the liver and is in part excreted in the urine, rendering urinalysis useless as a gauge of the patient's progress.

The selection of the anesthetic will depend on the surgical lesion and its location. General anesthetics, notably chloroform and ether, produce some degree of hyperglycemia and acidosis in normal persons which postoperative vomiting and food restriction intensify. In filtration anesthesia with novocain when the lesion is accessible to this method, is ideal. Spinal anesthesia is satisfactory when the lesion involves the pelvis or legs; some surgeons prefer it for all abdominal lesions, while others feel that the increased dose demanded for upper abdominal operations makes it more dangerous than inhalation anesthesia. Ethylene and nitrous oxide produce but little increase in the blood sugar content and as a rule cause but little nausea, allowing the patient to take and retain food comparatively early. If abdominal relaxation is essential to expediting and shortening the time of operation or to reducing the degree of surgical trauma the addition of a small amount of ether to the ethylene or nitrous oxide will secure it with a risk less than that entailed by prolonged manipulation. The after care as well as the preliminary preparation of the diabetic should be entrusted to one thoroughly conversant with the management and treatment of diabetes.

The successful solution of the perplexing problem presented by the surgical diabetic hinges upon the co-operation of the

internist and the surgeon, each of whom must be qualified in this particular field, since the joint knowledge and service of both are essential to it. The frequency with which gallbladder disease is associated with diabetes has inclined many to the view that a causal relationship exists between the two, the disease in the pancreas being held secondary to that in the gallbladder. The most frequent age for the onset of diabetes is fifty years or well within the common age incidence of gallstones while the longer duration of diabetes under the present regime of treatment allows greater opportunity for the development of gallbladder disease as well as increased occasion for its recognition. Regardless of this observation the improvement and, at times, disappearance of diabetic symptoms noted following the removal of diseased gallbladders, whether or not due to the favorable influence which the clearing up of foci of infection in general exerts upon this metabolic disorder, would seem to justify surgical intervention both as a prophylactic and curative measure.

The relationship of hyperthyroidism to diabetes presents points both of interest and difficulty. That the assimilation of glucose is disturbed in hyperthyroidism is shown by the glucose tolerance test and by the frequency with which glycosuria is noted both in primary hyperthyroidism and in adenomata with secondary hyperthyroidism. It is at times difficult to say whether or not the disturbed metabolism represents a true diabetes. Joslin and Lahey offer a somewhat different standard for the diagnosis of true diabetes in the presence of hyperthyroidism in requiring a higher blood sugar than for the standard diabetic. The dietary control in such cases is manifestly trying on account of the augmented metabolism due to the increase in thyroxin. The latter increases the danger of diabetic acidosis and renders insulin less effective, a situation analogous to that presented by infection. On a low carbohydrate diet there is an increase in the amount of acetone bodies in the blood on a high carbohydrate diet it may not be possible to

attain the objective of keeping the urine sugar free but it is possible and important to prevent the appearance of the acetone bodies. Insulin, diet, and iodine may be simultaneously employed in carrying such patients through operation after which they respond more readily to the diabetic regime.

The group of diabetics showing the greatest mortality is the one in which complications arise as a result of infection, cellulitis, carbuncles, and gangrene. Here, as elsewhere, an ounce of prevention is worth a pound of cure. The practice in some clinics of giving diabetic patients printed instructions regarding the hygiene of their bodies is a commendable one and could well be extended by the practicing physician to his known diabetic patients. Scrupulous body cleanliness is of paramount importance and is to be attained by daily bathing with soap and water, avoiding too vigorous rubbing. When the skin is unduly dry, emollients in the shape of oil or lanoline are useful. Light woolen socks or stockings, neither too short to produce pressure nor too long to allow wrinkling, should be worn with well-fitting shoes. Extremes of heat and cold are to be avoided. The care of blisters, minor skin injuries, corns, bunions, and ingrown nails should become the duty of the doctor, not of the patient. Chronic infections about the feet, bacterial and parasitic, should be searched for and treated. The subjective symptoms of deficient circulation in the feet and legs are discoloration, coldness, numbness, and pain regardless of the presence or absence of these warning symptoms, a determination of circulatory efficiency should be made in every diabetic, particularly if the patient has attained the age of fifty. The x-ray is of value in revealing the calcification of the larger arteries but does not show the condition of the capillary bed upon which the development of collateral circulation depends. There is no test, chemical or laboratory, which gives an accurate estimate of efficiency of collateral circulation. This is to be determined by clinical examination of the arterial pulsation, the

color, the temperature, and the reaction to various positions of the affected leg. Arterial pulsation may be absent in a foot in which collateral circulation adequately compensates for it. Such a foot, however, lives under a continual threat of disaster. In the light of the knowledge that practically all diabetics at or above fifty show some change in the peripheral arteries it would seem advisable to attempt by exercises similar to those of Buerger or by passive mechanical means to stimulate collateral circulation before the advent of complications.

Gangrene complicating diabetes occurs clinically in three groups, one in which the condition is primarily due to deficient circulation, one in which the condition is primarily due to infection, and one in which a spreading infection is engrafted or superimposed upon deficient circulation. Three types of gangrene are observed, the arteriosclerotic, the embolic, and what may be termed diabetic gangrene. The arteriosclerotic is similar to the senile gangrene of nondiabetic patients.

The embolic or thrombotic results from an embolus or occluding thrombus due to an acute infection. In the so-called diabetic gangrene, arterial occlusion has occurred slowly and adequate circulation has developed. A minor injury provides the wound of entry for infection, the resultant swelling shutting off so much of the blood supply as to cause gangrene. The deficient circulation is inadequate to a localization of the infection, its spread occurring along the cellular planes, veins, and lymphatics. In this group septicemia frequently occurs with high mortality. With the exception of the embolic or thrombotic type arteriosclerosis of both common and distinctive character forms the background of all diabetic gangrene. Aside from producing arteriosclerosis, diabetes prepares the soil for gangrene by its influence on the nutrition and metabolism of the tissues, the actual precipitation being due often to what might seem an inconsequential trauma. The treatment will depend upon its extent, disabling pain, determination of collateral

circulation, and the pressure and degree of infection

Time does not permit of a detailed discussion of the factors influencing choice of operation but they may be generalized as follows (1) incision and drainage is rarely indicated alone but may be combined with amputation of a toe in cases in which collateral circulation is sufficient to localize the infection to the region of the toe, (2) amputation of gangrenous toes may be undertaken (a) when there is a good pulsation in the dorsalis pedis artery, (b) when the gangrene is fairly well demarcated in the absence of pulsation in the dorsalis pedis artery providing the foot is warm and of good color especially when dependent, (c) when the diabetes is mild, the pain in foot is negligible and the gangrene and accompanying infection remain localized. Major amputations are indicated in cases presenting (1) definite gangrene of one or more toes in the absence of a dorsalis pedis pulse provided the foot or a part of the foot is cold and of poor color or provided there is a definite point of temperature change in the lower leg, (2) beginning gangrene with spreading infection involving the deeper structures of the foot, (3) deficient blood supply without actual gangrene in which pain is not relieved by conservative measures, (4) a viable foot as far as circulation is concerned but in which prolonged sepsis endangers life because of diabetes or complicating conditions. One may be pardoned for reiterating the statement as to the importance of mutual understanding and close co-operation of surgeon and internist in the treatment of surgical diabetes since such is probably the most important single factor in the successful management of diabetic gangrene.

Carbuncles in nondiabetics usually are present as localized areas of infection when death follows it is due to septicemia, metastatic abscesses and exhaustion. Localization of the infection depends upon the vitality and resistance of the patient. The relation between diabetes and infection is such that these protective qualities are deficient in the dia-

betic with the result that localization is absent or imperfect, large areas becoming involved in the septic process, from which the absorption of huge amounts of toxins augment the diabetic disorder with a breakdown of the patient's local and general resistance. Early and efficient treatment are imperative, this implies (a) rational treatment of diabetes, (b) the proper use of heat to hasten localization, (c) operation properly done. Operation is indicated as soon as the central portion of the lesion has softened. We employ a crucial incision, each limb of which extends to the margin of the infiltration. The skin flaps are undermined and the tissue showing purulent infiltration is excised. The remaining cavity is charred with the actual cautery, the point of which is thrust well out into the surrounding indurated tissue until its margin is reached. The resulting wound is packed with vaseline gauze and changed as needed for cleanliness. When the resulting defect is unusually large, pinch grafts are employed to facilitate healing when the granulations have become healthy. We have not employed vaccines, autogenous blood injections, methenamin, or x-ray therapy in the treatment of diabetic carbuncles and believe that if used at all, such usage should be in conjunction with the above outlined treatment.

The writer desires to acknowledge his indebtedness to the authors whose articles are listed in the bibliography and in particular to Drs McKittrick and Root from whose book *Diabetic Surgery*, he has liberally and literally quoted.

DIET AND DENTAL CARIES

RUSSELL W BUNTING, D D S , The School of Dentistry, University of Michigan

AS WE review the various pathologic conditions which commonly occur in the oral field, the treatment of which is specifically within the province of dental practice, we realize that of them all dental caries is the most important. If dental caries were a malignant disease terminating in the death of the individual, practically the entire population of the civilized world would long since have been wiped out. All that would remain would be about 5 per cent of civilized mankind, who seemingly are immune to the disease, and the inhabitants of uncivilized countries who notably are free from it. This scourge of mankind is not malignant. It does not kill but it does cripple and incapacitate a large proportion of people. Its effects are not confined to the teeth themselves but may also produce serious disturbances of the general health. It constitutes the almost sole avenue by which pathogenic bacteria may enter the tooth and pass through the pulp canal to invade the periapical tissue, thereby giving rise to foci of infection at that point. These root-end foci resulting from caries invasion undoubtedly are the most significant sources of systemic infection from the oral field. Concerning them Dr John A. Kolmer, professor of Medicine in Temple University, in discussing the causes of disease recently made this statement: "Without doubt, the systemic diseases that may arise, secondarily, from primary foci of infection about the tooth and gingivae take first place in importance."

Suffice it to say that at least the majority of physicians and dentists believe such foci to be responsible for disease in many other parts of the body, without inferring that the latter are always and solely due to focal infection."

The late Sir William Osler also made this significant statement: "There is not one single thing in preventive medicine

that equals mouth health and the preservation of the teeth."

If dental caries could be prevented or adequately controlled, the most significant forms of dental foci of infection would be prevented and the problems of medicine and dentistry relating to those forms of arthritis, nephritis, cardiovascular diseases, and diseases of the gastrointestinal tract which so often arise from such foci would be wholly eliminated. The significance, therefore, of the study of dental caries and the means of its prevention cannot be overestimated.

So many contradictory statements have been made regarding the nature of this dental disease and the means of its control that the present state of confusion of thought and uncertainty is quite understandable. It is apparent that many or all of the theories advanced have been wrong and serve only to add to the confusion. In order that we may have a clear understanding of the basic principles involved, we must realize that dental caries is wholly unlike other pathologic processes. In no other part of the body are exposed calcic structures decalcified by extraneous acids. It is a unique disease which does not follow the usual course of inflammatory reaction and tissue defense that are manifested by other diseases. The tooth plays an almost passive role in the process. Dental caries is in reality an injury, a progressive destruction of the tooth with the formation of cavity-like lesions which involve first the enamel and later the dentin. This destruction of dental tissues is not general but distinctly localized to those surfaces of the tooth where stagnation of the environmental fluids is favored. It never occurs on a continuously clean tooth surface. The active destructive principle is unquestionably some form of organic acid. These acids are not resident in the

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, May 12, 1938*

saliva but are formed on the tooth itself by the products of localized fermentation of carbohydrate food debris. There are many types of acidogenic bacteria in the saliva capable of breaking down carbohydrates to lactic acid but there are only a few that are also sufficiently aciduric to live in their acid products. Of these the most prominent is the oral *L. acidophilus*.

This organism has such a high correlation with the activity of dental caries that it may well be regarded as the specific bacterial factor. It is always present in the salivas of individuals having active caries, often in extremely high counts, and is consistently absent or extremely low in numbers when caries is inactive. The degree of such correlation is approximately 90 per cent. So close is this relationship that the *L. acidophilus* counts are now being used as a dental caries index with a very high degree of accuracy.

The activity of dental caries is variable. It occurs most commonly among civilized people. Many primitive races living on native foods are practically free from the disease. That immunity to the disease is not a racial characteristic is indicated by the fact that when such native tribes migrate into so-called civilized areas and adopt the diet of modern man, their teeth begin to decay with alarming rapidity.

Dental caries varies with age. It is most common during childhood and decreases in activity after the age of twenty. Dental caries is not determined by the hardness or softness of the teeth. The strongest teeth cannot successfully withstand the acids of caries if continually subjected to them, and soft teeth never decay solely because they are poorly formed. Many hypoplastic and imperfect teeth remain free from caries throughout the life of the individual. The structure of the tooth may have a relative effect on the process in that it may impede or accelerate the rate of caries, but it does not determine the occurrence of the disease.

Dental caries is not determined by the degree of cleanliness of the mouth. In the human mouth cleanliness is never absolute but relative only. As a rule the

cleaner the teeth the less active caries will be, but filth alone will not induce the disease. The presence of an aciduric bacterial flora is necessary to the process.

Dental caries is definitely controlled by certain unknown inherent characteristics of the individual. A small percentage of people are apparently immune to the disease. In them *L. acidophilus* is seldom found in the saliva and if implanted therein it soon disappears. As yet no immunologic principle antagonistic to the organism has been found in the saliva, but Philip Jay of Michigan has demonstrated in the blood of caries immunes a high agglutinin titer against it. This titer is low or absent in the caries susceptible individuals. Skin reactions to *acidophilus* filtrates have also been demonstrated in caries susceptibles. The great majority of people are more or less subject to the disease, especially during childhood. In them *L. acidophilus* grows in the saliva with varying degrees of activity somewhat proportional to caries activity.

The activity of dental caries is not associated with either a low calcium or low phosphorus intake or with deficiencies of these substances in either the blood or the saliva. Immunity to caries is not associated with consistently higher blood or salivary calcium and phosphorus values. The feeding of these inorganic salts for the prevention of dental decay is therefore wholly unsupported by the biochemical findings.

The opinion has been held by many that decay of the teeth is a localized evidence of dietary inadequacy and nutritional unbalance. A variety of hypotheses have been advanced in which certain food factors have been considered to be most important in this regard: avitaminosis, especially vitamins D and C, low calcium and phosphorus, and low alkalinity have each been advanced as most responsible for dental disease. It is claimed that by the feeding of any one or combinations of these food factors the teeth may be protected against caries.

Many feeding experiments have been conducted in which children have been

fed food concentrates in which one or the other of the so-called protective foods have been accentuated and variable degrees of dental caries reduction have been reported. At Michigan we have fed viosterol, calcium and phosphorus, and vitamin C to children under carefully controlled conditions, but we were unable to discern any appreciable reduction of caries. Furthermore, the salivary *Lactobacillus* counts, instead of dropping as a result of such feeding measures, increased at first and then receded to their former levels.

For the most part, the objective of such feeding programs is the increasing of the resistance of the teeth against dental caries. This hypothesis is untenable. Dental caries is not determined by the strength or resistance of the tooth itself. Furthermore, we frequently see children who have been raised on the most adequate and well-balanced diets who have from earliest infancy had all the protective foods which could be recommended by pediatricians and yet their teeth have suffered from extensive caries. Conversely, many children who have been malnourished throughout life may have little or no decay of the teeth. In our experiments we have observed an almost complete arrest of dental caries in a group of over 300 children who have been raised on inadequate diets which were low in all the vitamins, low in calcium and phosphorus, and low in calories. Certainly, for them the control of dental disease could not be attributed to the protective effect of any of these substances. It is because of these facts that we have been unable to accept the dictum that dental caries is a deficiency disease or that the provision of an adequate nutrition will necessarily insure a freedom from that disease. Unquestionably, during the developmental period at least, the provision of adequate amounts of inorganic salts and activators of inorganic salt metabolism such as sunlight, viosterol, and cod-liver oil is highly important for the formation of good bones and teeth, but there is no adequate evidence that the provision of any or all of these principles

is of any practical value in the prevention of dental caries.

Although the Michigan group were unable to obtain any appreciable control of dental disease by the addition of minerals and vitamins to the diet, they have obtained striking and highly gratifying results by the elimination of sugar and starch from the daily dietary intake. In this manner the *Lactobacillus* count may be promptly lowered and dental caries may be definitely arrested in a great majority of cases. In some the withholding of sugar alone will suffice, but in others it is necessary also to reduce the starch. As previously mentioned, we have observed over a period of several years a group of approximately 300 children in an institution where the feeding is closely supervised. These children have received a diet that was nutritionally unsatisfactory and did not contain adequate amounts of the protective food factors. Although the total diet was nearly 50 per cent starch, practically all free sugar was eliminated. No sugar was allowed on cereals or in beverages and only a minimum amount was used in cooking to make foods palatable. All forms of candy and sweetened desserts were prohibited. It was found that the children so fed were in good physical condition with but slight evidences of undernutrition and that 80 to 90 per cent of them were practically free from oral acidophilus and dental caries. These figures are much higher than any other human experimentation in caries control thus far reported. A small number, probably those who were highly susceptible, continued to have a moderate growth of *L. acidophilus* and occasional dental caries. The great majority showed every evidence of an arrest of dental disease.

When candy and free sugar were fed to a group of these children the salivary acidophilus was immediately excited to a high degree of activity and after a period of several months new dental caries appeared. In a few individuals who were definitely caries-free, the acidophilus counts remained low in spite of the increased carbohydrate intake. In them

dental caries did not occur. These same observations have been made on children in other institutions and in private homes.

From these and other evidences which we have elsewhere reported we are led to the conviction that the most important etiologic factor of dental caries is the presence in the mouth of specific types of acid producing bacteria which determine its occurrence irrespective of all other factors. It is true that cleanliness, hardness of teeth, the physical qualities of the diet, and certain other considerations may determine the rate and extent of the disease, but the initial onset and the progress of the disease are determined most of all by the degree of activity of the oral bacterial factors without which dental caries apparently cannot occur. Furthermore, in the control of dental caries we have as yet found but one method of reducing the specific oral bacteria, namely, the reduction of sugars and starches in the diet.

We recognize the definite limitations of this procedure in any wide spread control of the disease. Although the elimination of sugar alone from the diet will in a large majority of cases greatly reduce or entirely arrest caries it has but a limited usefulness as a preventive measure. When we realize the extent to which sugar has been incorporated into the daily dietary habits of civilized man, we must admit that the possibility of any national movement to forego the use of sugar and candy is quite remote. During the past year there has been a substantial increase in sugar consumption in this country and it is reported that over two billion pounds of candy have been sold to the American people.

Even the fear of dental caries will not combat an enterprise of such magnitude as this.

That such a high sugar consumption is not necessary to life and health is indicated by the fact that our forefathers who pioneered the land in which we live were raised on an annual consumption of a paltry twelve pounds of sugar per capita.

For those individuals who are deeply concerned over the rapid destruction of their teeth by caries and who are willing to forego the eating of sugars and highly fermentable starches, one tangible means of relief is offered. At Michigan a caries control clinic is now in operation where patients are advised, under the direction of their physician, to reduce their sugar and starch intake and the effectiveness of such procedures is determined by bacterial counts of oral acidophili. This procedure has been very effective when patients have co-operated in carrying out the dietary prescriptions. This service has even been extended to those at some distance from Ann Arbor by the examination of salivary samples sent to the laboratory by air mail. Those who wish to avail themselves of this aid to caries prevention may do so by writing the School of Dentistry, University of Michigan.

We sincerely hope and expect that through further study and experimentation some other more practical method may be found by which *L. acidophilus* overgrowths can be reduced or eliminated from the mouth without such drastic dietary restrictions. In our opinion the greatest hope of caries control lies in the development of some more practicable means of limiting the growth of the specific organisms in the mouth.

THE END OF A DREAM

Last vestiges of the Federal resettlement administration's experiment with co-operative health groups in Los Angeles County have disappeared into thin air according to the Los Angeles papers. Two starts with two different groups have been made since 1936 with persons who had borrowed money from the AAA privi-

leged to pay \$2 a month for group medical care. The \$2 monthly was to be paid by the Government, and later repaid by the beneficiary along with his original loan. Private concerns were to provide the medical aid, but insufficient remuneration brought about dissolution of the health groups and apparently the whole idea.

TYPE III PNEUMOCOCCUS PNEUMONIA

The Effect of Para-Aminobenzenesulphonamido Pyridine in Treatment

EDGAR A LAWRENCE, M D , New York City

SINCE the introduction of M & B 693, para - (aminobenzenesulphonamido) pyridine by Whitby,¹ there have been a number of reports concerning its effect both clinically and in vitro Fleming² has described its antibacterial action in vitro and points out that probably the best results would be obtained in the presence of immunized blood Telling and Oliver³ point out that the effect of the drug in the human is to cause a decapsulation of the pneumococci and thus loss of type specificity They were able to restore type specificity by repeated mouse passage

In reporting the two following cases, we are attempting to show both the clinical and bacteriological effects of M & B 693, and also to demonstrate that the type specificity of the pneumococcus is lost prior to its decapsulation Sputa were examined at intervals during the administration of the drug and the following procedures on each specimen were carried out

- 1 Quellung reaction with the fresh specimen of sputum
- 2 Direct smears and culture of fresh sputum on artificial media
- 3 Mouse inoculation
- 4 Quellung reaction with the mouse's peritoneal exudate
- 5 Repeated mouse passage to determine the effects on the organism

Case Reports

Case 1 A white male, aged 78, was first seen on October 23, 1938, complaining of an acute coryza His past history was essentially negative save for an attack of Type III pneumococcus pneumonia in 1935, involving both the left upper and lower lobes, from which he made a slow but uneventful recovery Since that time

he has shown pneumococcus Type III on several occasions both in the sputum and in the throat He has always been a moderate drinker of alcohol

The present illness started with an acute upper respiratory infection which

finally, on October 25, 1938, led to involvement of the left lower lobe, with rusty and, at times, bloody sputum, fever of 102 2° F, rapid shallow respirations, and a pulse rate of 96

On physical examination, he was acutely ill Signs were entirely localized in the left lower lobe where there was suppression of breath sounds and many fine moist râles The diagnosis of lobar pneumonia was made and confirmed by a portable x-ray which showed mottling and early consolidation of the affected lobe The urine was negative and there was a relative leukopenia of 5,300

The sputum was tenacious, frankly bloody, and yielded pneumococcus Type III by the Quellung reaction and also by mouse inoculation. The organisms were present in large numbers, and culture on blood agar, a pure growth of Type III pneumococcus was obtained in 20 hours. M & B 693 was started on the second day of the pneumonia, the patient received 1 gram (grains XV) of M & B 693 every four hours until a total dose of 19 grams had been given. He received no other medication other than codeine grain $\frac{1}{4}$ to allay the persistent cough.

The clinical course of the patient was dramatic. After 4 grams of M & B 693 had been given, the temperature dropped from 102.2° F to normal by crisis, the pulse returned to normal levels, the respirations which had been as high as 40 per minute returned more slowly to normal and the patient was entirely comfortable. There was no further elevation of the temperature and the recovery was uneventful. The only untoward results noted from the administration of M & B 693 was a slight cyanosis, nausea, and hiccough after 12 grams had been given. The nausea abated with continuance of the drug but the hiccough continued. Within 24 hours of cessation of the drug, the hiccough and cyanosis had entirely cleared up.

After 4 grams of the drug had been administered, the sputum, which was now rusty, was re-examined by the Quellung method. Though the organisms were still present in abundance, there was no Quellung reaction with any of the diagnostic sera. The capsules were present. On blood agar, after an incubation of 48 hours, one colony of pneumococcus was found, which on subculture in blood broth still failed to reveal a positive Quellung reaction in any of the diagnostic sera. The capsules were, however, demonstrable by a Hiss capsule stain.

After 9 grams of M & B 693 had been administered, the sputum was less rusty and fewer organisms were seen. The capsule now was not demonstrable, the organisms were pleomorphic and the

Quellung reaction was, therefore, entirely negative. There was no growth on any artificial media but on mouse inoculation, death was produced in 40 hours. A positive culture of pneumococcus was obtained from the mouse's peritoneum, heart, and brain. The colonies were of the dew drop variety and typical of pneumococcus Type III, however, though a capsule was demonstrable, no Quellung reaction was obtained. 0.2 cc of the peritoneal exudate was injected into a second mouse, death occurring in 9 hours. However, the Quellung was still negative. With subsequent subinoculation, the organisms from the third mouse showed an occasional positive Quellung with type specific antipneumococcus Type III serum. Mouse 4, which died in 10 hours, revealed organisms that were practically all positive by the Quellung reaction with diagnostic Type III antiserum.

After 10 grams of the drug had been administered, the sputum was thin and watery with only an occasional purulent fleck. Only an occasional organism was demonstrable. On blood agar no growth of pneumococci occurred. The virulence of the organism was apparently so low that on mouse inoculation no death occurred. The first mouse was killed and the peritoneal exudate was injected into a second mouse that showed apparently no ill effects whatsoever.

Case 2 * A white male, aged 65, was seen on October 26, 1938, by his private physician complaining of feeling chilly and uncomfortable. His past history revealed chronic bronchial asthma and a long standing hypertension (B P 180/70) complicated by intermittent attacks of auricular fibrillation. He was an inveterate smoker and addicted to alcohol in large quantities. The onset of the present illness was hard to determine but apparently he noticed extreme dyspnea during one of his usual asthmatic attacks that failed to subside.

On physical examination, he was acutely ill, cyanosis was mild but definite,

* I am indebted to Dr. Leo Price for allowing me permission to report this case that was seen by me in consultation.

the breathing was shallow and rapid. Auricular fibrillation was found to be present. Apart from the loud moist râles and rhonchi all over the chest, signs were localized over the left lower lobe where there was dullness and many fine crepitant râles. A diagnosis of lobar pneumonia was made. The sputum revealed a Type III pneumococcus and it was decided to administer both M & B

603 and Type III Antipneumococcus Rabbit Serum. The skin and ophthalmic tests were negative and there was no demonstrable sensitivity by the intravenous test. However, after only 1.0 cc of the rabbit serum had been administered, marked cutaneous wheals appeared and a short time later profound dyspnea, substernal pain, and urinary urgency were noted in spite of repeated injections of adrenalin. It was thought advisable to discontinue serum therapy. M & B 603 was given in an initial dose of 2 grams (grains XXX) and 1 gram (grains XV) every four hours until a total dose of 25 grams had been administered. Oxygen was used for some 12 hours early in the disease to combat the cyanosis.

The pulse during the first day of the disease ranged between 118 and 140, the

temperature remained constantly between 102.2° F and 103° F, and the respirations between 30 and 36. M & B 603 was started late in the first day of the disease. Crisis occurred after 10 grams of M & B 603 had been given and the temperature on the third day of the disease was 97° F, pulse 88, and respirations 22. The temperature continued to be flat, the pulse slowly dropped to 72 and the respirations to 19. Convalescence was uneventful. Digitalis was given in view of the fibrillation but no other drug was used in conjunction with the M & B 603. Only slight nausea was observed during the administration of the drug.

A similar study was done with the sputum as in Case No. 1. The sputum was rusty and large numbers of Type III organisms were found by the Quellung reaction. It is interesting to note that after 3 grams of M & B 603 had been given, the Quellung reaction was still positive and the temperature remained high. After 10 grams had been given, crisis occurred and it was found that the Quellung had now become negative for any type. Following the loss of type specificity, the capsule disappeared in subsequent specimens and was restored first by repeated mouse passage and followed by the re-establishment of the type specificity in precisely the same manner as in Case 1.

Comment

The use of M & B 603 in the treatment of these two cases of Type III pneumococcus pneumonia appears to possess definite value. In both cases crisis occurred with rapid abatement of symptoms and recovery was uneventful. It is of note that both cases occurred in men over the age of 65, both were addicted to alcohol and, in Case 2, hypertension, auricular fibrillation, and chronic bronchial asthma complicated the picture.

It is interesting that crisis occurred after only a small quantity of the drug had been administered, possibly demonstrating the direct action of the drug on the invading organism regardless of the concentration of the drug in the blood.

(Case 1 received only 1 gram as an initial dose) The only untoward symptoms produced by the drug were nausea, hic coughing, and mild cyanosis, all of which rapidly cleared upon cessation of the drug. The toxicity of the drug, as far as our present knowledge is concerned, appears to be much less than that experienced in the use of sulphanilamide.

Bacteriologically, in the reported cases, the main action of the drug is first to cause the loss of type specificity of the pneumococcus which is then followed by complete decapsulation of the organism and finally by its inability to grow either on artificial media or in the mouse's peritoneum. We are unable to state whether this apparent inability of the organism to grow is due to a bacteriostatic or bacteriocidal action of the drug. It would seem, however, that there is a definite bacteriostatic action since improvement is noted so early in the disease. On mouse passage the reverse process is noted, first the reappearance of the capsule and second the re-establishment of type specificity. There was no demonstrable change in the type of the original organism in spite of the complete decapsulation and mouse passage.

Summary

1 Two cases of Type III lobar pneumonia are reported with recovery.

2 M & B 693 in the above two cases appears to possess definite value in the treatment of Type III pneumonia and deserves further clinical trial in the therapy of not only Type III pneumonia, but of other types as well.

3 The action of M & B 693 on the pneumococcus is first to produce the loss of type specificity and then complete decapsulation. This process is reversed with repeated mouse inoculation, the capsule reappearing first, and finally, type specificity.

4 No transmutation of pneumococcus type was noted during this loss and re-establishment of type specificity.

I am indebted to Miss M. E. Wilder, A.B., for her assistance and originality in carrying out the bacteriological studies.

REAL MEDICINE STILL WINNING

The voters of California and Colorado November 8 by overwhelming majorities emphatically rejected proposals made in those states to undermine the structure of scientific medicine, as reported in the *A M A Journal*. In California an initiative humane pound law so-called proposing to cripple scientific research by hampering animal experimentation, was decisively defeated. In Colorado an initiative measure proposed by a group of chiropractors to debase the quality of medical care in the state by repealing the basic science act and by destroying other safeguards that have been erected to assure adequate and scientific medical service, was met by an avalanche of negative votes running as high as ten to one in some counties.

In Oklahoma an initiative measure that would have sanctioned practices not conducive to public welfare failed to get on the ballot, because of court action instituted by the medical profession. In Ohio a chiropractic initiative somewhat similar to the Colorado initiative died aborning. The

cultist sponsors apparently becoming disheartened shortly after the proposal was submitted to the attorney general for his approval as to form. Petitions in Ohio were not circulated and the proposed initiative measure was not submitted to the people for a vote.

The medical associations in the states named assumed the lead in thwarting the selfish interests behind these proposals interests that would subordinate the public welfare to their own private ends.

In California and Colorado the state medical associations, aided by many lay and other professional groups and by public-spirited citizens informed the people fully of the dangers implicit in the proposals. To bring these dangers to the attention of the voters necessitated great sacrifices of time and money but the results show that such sacrifices were well worth while and indicate that an informed electorate will support scientific medical care under proper legal and ethical safeguards.

BLOOD CULTURE: AN AID IN DETERMINING TYPE IN LOBAR PNEUMONIA

With a Note on Sulfanilyl-Sulfanilamide in Type III Lobar Pneumonia and Septicemia

R D ROECKER, M D , and JOSEPH MILLETT, M D ,
Meadowbrook Hospital, Hempstead, New York

ALL cases of lobar pneumonia admitted to the medical service of the Meadowbrook Hospital within ninety-six hours after onset of symptoms are treated as emergencies. The sputum is immediately typed, a blood culture is taken, and routine treatment—consisting of forcing of fluids, oxygen, sedative, etc.—is instituted. If the sputum reveals Type I, II, V, or VII organisms, the appropriate serum is given intravenously in the recommended doses immediately after skin and ophthalmic tests for sensitivity have been done. Severely toxic patients have been benefited by serum even ninety-six hours after onset. Our results have been uniformly good and correspond to the results reported by other workers in larger series of cases.¹⁰

Pneumococcus Type III has generally been recognized as producing a lobar pneumonia of marked severity. At the present time, there is no specific horse serum available for the treatment of this disease. Rabbit serum which has given such great promise as a more potent agent in the serum treatment of pneumonia has been found ineffective in treating Type III lobar pneumonia.¹¹ Because of the results obtained in the last case⁸ of Type III pneumonia admitted to the Meadowbrook Hospital in the spring of 1937, it was decided that all subsequent Type III pneumonias would be treated by chemotherapy. The scope of these investigations was also extended to include Group IV cases for which serum was not available. (Those sputums containing pneumococci which showed no capsule swelling with Type I, II, III, V, VII, and VIII antisera are classified as Group IV.) Disulon was chosen as the chemothera-

peutic agent in a selected series of Group IV cases because of its reported low toxicity.

Hoerlein¹ was the first to point out the efficacy of original Prontosil against the Type III pneumococcus and suggested that these organisms might be chemotherapeutically classified as streptococci. Using sulfanilamide in experimental intraperitoneal Type III infections in mice, Rosenthal² and Cooper, Gross, and Mellon³ reported distinctly encouraging results. Cooper and Gross⁴ were able to save a large majority of their rats with a Type III lobar pneumonia experimentally induced.

Clinically, the results were equally encouraging. In a series of nineteen Type III lobar pneumonias, which carries a high mortality in the Pittsburgh area, Heintzelman, Hadley, and Mellon⁵ reported that of nine patients receiving sulfanilamide seven lived and two died, while of the remaining untreated cases eight died and two recovered. Millett,⁶ at the Meadowbrook Hospital, induced a crisis with sulfanilamide in a Type III lobar pneumonia twenty-four hours after onset, which was contrary to the general experience with this disease in a series covering two winters since the establishment of the hospital.

Gray, Buttle, and Stephenson⁷ reported that sulfanilyl-sulfanilamide was one-half as toxic and just as effective as sulfanilamide against streptococcal infections in mice. Rosenthal,⁸ reporting on the efficacy and toxicity of a series of closely related chemotherapeutic agents of the sulfonamide type, found that 4(4'-aminobenzol-sulfonamide)-benzol sulfonamide (sulfanilyl-sulfanilamide) was one-fifth as

toxic and just as effective as sulfanilamide against experimentally induced streptococcal and meningococcal infections in mice. Sulfanilamide was superior to sulfanilyl sulfanilamide against Type I, II, and III pneumococcal infections in rats and mice. Barlow⁹ confirmed Rosenthal's results regarding the toxicity of Disulon and its efficacy in streptococcal infections.

The formula of sulfanilyl sulfanilamide compared to sulfanilamide is as follows

It is a white crystalline compound, difficultly soluble in cold water (0.01 per cent), but much more soluble in hot water.

The following case of Type III lobar pneumonia and septicemia is reported from the medical service because of a dramatic result in a dangerous infection treated with a new chemotherapeutic agent.

Case Report

A fifty-eight-year-old white female was admitted with the complaint of stabbing pain in the right chest, aggravated on breathing and coughing, of 12 hours duration.

The present illness dates back to three weeks ago when she had a sore throat which lasted for two weeks and apparently responded to home remedies. At 2 A.M. of the day of admission, the patient was awakened from her sleep by a stabbing pain in the right chest beneath her breast. She felt feverish and began to cough. In a few hours she had a temperature of 104° followed by a severe chill. The patient had a severe headache and vomited once before admission.

Past history revealed that the patient had moderate dyspnea on exertion—climbing one flight of stairs—and orthopnea requiring two pillows. There was no history of peripheral edema. Many years ago she had had double pneumonia. She was Gravid IX, Para VIII. A miscarriage 15 years ago was carried through

without complications. The cause was unknown. System review and family history were noncontributory.

Physical examination revealed a white, thin, moderately developed, Polish female, with evidence of recent loss of weight. She appeared acutely ill. There was a short, hacking, slightly productive cough which aggravated the pain in the right chest. The lips were cyanotic. The teeth were markedly carious and the pharynx was acutely injected. The thyroid was palpable.

Examination of the chest revealed a heart within normal limits by percussion. There were no murmurs heard. The rhythm was regular. The rate was rapid, 110, and the blood pressure was 120/70. Examination of the right chest posteriorly revealed dullness to percussion from the angle of the scapula to the base with diminished breath sounds and numerous medium moist crepitant râles at the base and in axilla. The left chest was not impaired to percussion and there were numerous coarse râles at the base. The abdomen was somewhat distended but otherwise negative. The extremities were negative.

Laboratory (December 21, 1937)

| | | | |
|------------------------|--------------|---------------------------------|------------------------------|
| Urine | Sp Gr 1.020 | acid sugar and albumen negative | The microscopic was negative |
| Blood | Hb | —68% | |

| Throat swab and sputum | A few | Group IV pneumococci | |
| Blood chemistry | N P N | 43 | |
| | Creatinine | 1.5 | |
| | Sugar | 118 | |
| | Chlorides | 428 | |
| Wassermann and Kahn | | Negative | |

Clinical Course The patient was acutely ill. She was given routine treatment for pneumonia. Sulfanilyl sulfanilamide was given in doses of ten grains four times a day. The temperature was septic in character ranging from 99° to 104°.

A portable x-ray of the chest revealed pneumonic consolidation of the lower portion of the right upper lobe with a bronchiolar pneumonia of the right lower lobe

PLATE I

On the morning of the fourth day (Dec 24), it was noted that a routine blood culture had not been taken on admission and one was taken immediately. The laboratory report of the blood culture by Miss Irene Kirkman, M S, was as follows

There was no growth on the plate. The broth showed a profuse growth of long heavy filaments. These filaments stained solidly with Gram stain. In a few places there seemed to be heavy counter-stained strands with small particles of Gram stain which suggested the possibility of pneumococci (Plate I). For this reason the Quellung typing was set up. The strands stained just as heavily with methylene blue and suspicion that they were fungi was entertained.

Sub-cultures were made to study the organism further. The next day typical colonies of pneumococci were found. On typing, these were found to be Type III pneumococci (Plate II). The dose of sulfamyl-sulfanilamide was increased to 60 grains per day on December 25 and

was continued up to and including December 30.

The seventh day after admission and the institution of sulfamyl-sulfanilamide therapy and two days after the dose of the drug had been increased, the temperature dropped to 100° and remained at 100° to 100.4° for twelve more days. Subsequent sputum typings still revealed Group IV pneumococci. Three more x-rays of the chest, taken several days apart, revealed a slowly resolving pneumonia. Two more blood cultures taken subsequently revealed no growth.

Discussion

The case illustrates quite well the importance of following a definite routine in lobar pneumonia from the standpoint of diagnosis, treatment, and prognosis. Because a blood culture was not taken on admission, it is impossible to tell when invasion of the blood stream took place. The severity of the clinical picture and the septic temperature lead us to believe that the blood stream was infected from

PLATE II

the onset of symptoms. Fortunately for the patient, she received sulfamyl-sulfanilamide from the time of admission. The mortality of Type III septicemia (98 per cent) and the remarkably heavy

growth in the blood culture leads one to believe that the recovery was due to the chemotherapeutic agent and not to mere fortuitous circumstances.

The patient received a total of 550 grains of Disulon over a period of 10 days with no ill effects. With continued clinical improvement the cyanosis of the lips disappeared in spite of continued sulfanilyl sulfanilamide therapy. There were no skin reactions. The CO_2 combining power of the blood was 43 vol per cent on the completion of drug therapy. A blood count taken two days later showed 9,900 white blood cells, with 78 per cent Polys, 20 per cent Lymphocytes, 1 per cent Monocytes, and 1 per cent Eosinophils. The urine was negative. No subjective symptoms such as loss of appetite, nausea, or vomiting, and dizziness were elicited. A neurological examination 21 days after cessation of treatment revealed no subjective symptoms of the extremities, or objective findings such as sensory or motor changes, in-co-ordination, paralysis, or changes in reflexes. The neurological examination was undertaken because we were informed that Rosenthal had reported a small number of cases of peripheral neuritis in a limited series of gonorrhea cases treated with 60 grains of sulfanilyl sulfanilamide a day for a period of 10 days. The symptoms in his cases appeared one to two weeks after cessation of treatment.

There were 30 cases of Group IV lobar pneumonias treated with sulfanilyl sulfanilamide. The average dose per patient in this series was 300 grains for an average of 7 days. The only complication noted was a rather intense cyanosis in five cases. There was no alteration in the red or white count, fever, or dermatitis. No peripheral neuritis was noted in these cases. The CO_2 combining power in several cases had dropped to 45 volumes per cent. This was easily counteracted by sodium bicarbonate. A series of 20 cases of Group IV pneumonias treated with sulfanilamide revealed approximately the same result. We are able to state that neither sulfanilyl sulfanilamide nor sulfanilamide in a small series of cases of

Group IV pneumonias, had any marked toxic effects. We also found that both compounds had no influence on the clinical course of Group IV pneumonia.

Bacteremia influences the prognosis of lobar pneumonia unfavorably. Cecil¹² found that the death rate for all bacteremic cases (Type I, II, and III) was definitely higher than for the cases with sterile blood cultures.

Tighlman and Finland¹³ analyzed 1,586 cases of lobar pneumonia associated with specific pneumococci of Type I to XXXII (Cooper) in which cultures of the blood were made during the acute state of the disease or at autopsy. In their extensive and interesting study they found that for each type the death rate in the cases in which the blood cultures were positive was two or more times as high as in the cases in which the blood cultures were sterile, and for all types it averages almost three times as high. There were 118 cases of Type III lobar pneumonia with septicemia in their series with a mortality rate of 98 per cent. One hundred and forty four cases of Type III lobar pneumonia with negative blood cultures showed a mortality rate of 40 per cent. Solomon and Curphey¹⁴ have stressed the importance of the blood culture in the diagnosis of streptococcus septicemia as a late complication of pneumococcus lobar pneumonia, when other causes for rise in temperature have been ruled out. The importance of this test from a prognostic standpoint is impressive inasmuch as seven out of eight patients with this complication died.

In lobar pneumonia, blood cultures are always not only necessary for prognosis but frequently they are necessary for diagnosis. This is borne out most strikingly in this case, where the throat swab and sputum revealed Group IV pneumococci, while the blood culture showed a heavy growth of Type III. Doskof¹⁵ at the Meadowbrook Hospital reported a similar occurrence. A patient recovering from a nonspecific infection of the throat whose temperature was flat at 89°F , had a sudden chill, temperature 104° , and pain in the right chest on breathing

Physical signs at the right base were suggestive, the sputum sent to the laboratory for typing revealed Group IV pneumococci. A blood culture was taken routinely.

The next morning the laboratory reported the blood culture to contain a pure growth of Type II pneumococci. Intravenous treatment was immediately instituted with New York State Type II serum and in 12 hours the temperature fell from 104° to normal. Type II septicemia has a mortality rate of 76 per cent.

In the spring of 1938 a twenty-five-year-old Negro was admitted with a right lower lobe pneumonia of twenty-four hours duration and a temperature of 104°. The sputum contained Group IV pneumococci.

The routine blood culture revealed a Type I septicemia. Eight hours after the administration of 150,000 units of New York State Type I serum the temperature was normal and the clinical course was uneventful.

Summary

1 A severe case of Type III lobar pneumonia and septicemia, a disease which carries a mortality rate of 98 per cent, is reported having recovered after the blood stream had been sterilized by a new chemotherapeutic agent—sulfanilyl-sulfanilamide (Disulon).

2 Blood cultures are necessary frequently as diagnostic procedures, always for prognosis. Where the sputum typing may be of no assistance in diagnosis, the blood culture may reveal an infection which can be specifically treated. The early diagnosis may mean the difference between death or recovery.

3 The importance of careful laboratory evaluation of atypical material is stressed.

4 Sulfanilamide and sulfanilyl-sulfanilamide (Disulon) did not influence the clinical course in a small series of Group IV pneumonias.

5 New chemotherapeutic agents should be used with caution, until clinical evaluation is complete.

THE RHEIN MEMORIAL LECTURE

Dr Walter E Dandy, Adjunct Professor of Neurological Surgery, The Johns Hopkins University Medical School and Hospital, Baltimore, Md., has been selected to deliver the Rhein Memorial Lecture before the Pathodontia Section, First District Dental Society, New York City, at the Academy of Medicine, 2 East 103d Street, on January 16.

Lecture title "Pains in the Head and Face"

An informal dinner in honor of the essayist will be given at the Academy of Medicine prior to the scientific session. Time 6 30 P M.

Dining accommodations at the academy are limited. To avoid disappointment please mail your reservation and check for \$1.50 immediately to Dr Daniel M. Kollen, Secretary, 24 West 59th Street. Telephone Wickersham 2-2670.

TONICS AND SEDATIVES IN NEUROLOGIC PRACTICE

HUBERT S. HOWE, M.D., New York City

THE term "tonic" has a rather nebulous meaning and the common question, "Doctor, what is a good tonic?" is about as easily answered by a physician as the query, "What is a good tool?" would be by a mechanic.

A tonic measure may be defined as an undertaking designed to produce a normal degree of vigor and well being.

Before effective tonic measures can be applied it is necessary to determine the cause of the depletion and lack of stamina. Is the cause of the patient's frailty a constitutional disease or local infection, the depletion following an illness, an anemia, malnutrition, vitamin deficiency, or an abnormal mental state?

The purpose of this paper is primarily to describe briefly the so-called tonic and sedative remedies of use in neurologic practice, with some reference to their indications, contraindications, and idiosyncrasies.

Tonics

When the specific indication for a tonic is not clear, refuge is frequently taken in the syrup of hypophosphites. The virtue of the hypophosphites seems to have little pharmacologic basis, but they have the value of popular conviction, a virtue which cannot be entirely disregarded.

The accelerated metabolism and heightened nervous irritability produced by thyroid overcome fatigue and produce a feeling of increased efficiency welcomed by many debilitated individuals. Patients with a mild depression severe enough to interfere with the pursuit of their occupation may be sufficiently stimulated by thyroid so that they can return to work. Small doses of thyroid will cause an increase in physical vigor and mental activity, but thyroid should not be used for this purpose except for periods of short duration. Thyroid administration causes an increased excretion

of calcium and magnesium and may thus produce a negative calcium balance. Instances of thyroid addiction are occasionally encountered, and, while easily recognized, if the symptoms are pronounced may escape detection when the complaints are mainly excitability, lack of stamina, and an increased tendency to fatigue.

Intravenous injections of suprarenal cortex hormone have been recommended by Leyton for the treatment of debilitated individuals with low temperature, blood sugar, and blood pressure. I have had no personal experience with this preparation as a tonic, but have never observed benefit resulting from the use of suprarenal gland substance by mouth.

The tonic action of insulin is of value for increasing the weight of persistently thin people. For this purpose ten units is given fifteen to thirty minutes before each meal. This must, of course, be accompanied by a liberal diet. Insulin is not as valuable in producing a weight increase in individuals of normal standard as in those who are underweight.

Strychnine has considerable value in increasing muscular tone and the activity of the spinal reflexes. It is useful therefore in weakness of the bladder and rectal sphincters due to lowered activity of their respective centers in the spinal cord and in the impotence encountered in individuals using alcohol or barbituric preparations.

Strychnine is of value in some debilitated patients with poor muscular tone and decreased deep reflexes. The sulphate is the salt usually employed, but ordinarily in insufficient dosage. The average single dose should be $\frac{1}{30}$ of a grain, with $\frac{1}{4}$ (one-quarter) grain as the maximum daily dose.

Caffeine is of value as a stimulant for some depressed and debilitated individuals. The depression experienced on

*Read at the Annual Meeting of the Medical Society of the State of New York
New York City May 11, 1938*

awakening after the use of hypnotic drugs, overindulgence in alcoholic stimulants, or the low spirits of patients with a depressive psychosis are alleviated by two or three grains of caffeine citrate administered on awakening.

Caffeine is of some use for the prevention of the dizziness, disturbances of consciousness, or convulsive attacks of cerebral arteriosclerosis. In clinical experience caffeine causes little if any elevation of blood pressure and is not contraindicated in hyperpiesis.

In doses of 5 to $7\frac{1}{2}$ grains caffeine citrate is of use for the relief of the fatigue type of headache and also for the alleviation of some cases of migraine.

Caffeine has a stimulating effect on the centers of the spinal cord exactly similar, but not as pronounced, as that of strychnine.

Benzedrine sulphate is an important stimulant. It has a distinct effect on the vegetative nervous system and particularly upon the pulse rate and blood pressure. Individuals who do not take this drug constantly may have an increase in blood pressure (both systolic and diastolic) of 10 to 30 mm which does not return to normal for several hours. On continued administration less marked or negligible elevations occur. The pulse rate acceleration averages 20 to 40 beats, and continues high after constant administration for many months. Many patients are aware of palpitation and state that exertion which did not formerly produce fatigue and dyspnea is noted while they are using benzedrine. Diminished tone is noted in the gastrointestinal tract. Many patients complain of its constipating effects, whereas the spastic and cramp-like contractions are relieved. A loss of appetite and dryness of mouth are frequently experienced.

The principal beneficial effects are due to its psychic action, which are frequently dramatic. Subjectively there is a change of mood, which tends to euphoria. The patient notes increased self-confidence, initiative, and mental poise. Depression is lessened and there is a pronounced

impulse to talk. The processes of thought are accelerated and some patients complain of a blunting of memory for recent events. Stimulation of the cerebral centers produces insomnia and restlessness. Sargent and Blackburn have shown an improvement of intelligence test scores, and Bradley has observed better performances in children with behavior disorders.

Many individuals are unable to take benzedrine, as even small doses (5 mg) produce extreme nervousness, palpitation, vertigo, and excitement which have been described by one patient as "going crazy." It is recommended in narcolepsy, depression (without anxiety or restlessness), exhaustion, seasickness, for the sleep disorders, oculogyric crisis and tremor in patients with encephalitis, and as a substitute for alcohol in chronic alcoholism. The euphorizing effects are lessened on continuous administration, but many patients find them sufficiently desirable to continue its use for many months. No instance of true addiction has come to my attention, though many authors express warnings of this possibility.

Benzedrine should not be used indiscriminately or without observation of the patient. It is a comparatively new drug and there is much to be learned about it.

Further experience will doubtless show its value to be principally in occasional use.

The most important of all tonics is a well-balanced diet. Of all animals man has probably the poorest diet as the food consumed depends almost entirely upon the caprices of his appetite. Barring accidents, longevity is principally a matter of nutrition. Biologists attribute the long life of the Sequoia trees in California to the fact that in that locality they have been able to obtain sufficient rootage to furnish the necessary nourishment. A diet having an energy value of 3,000 calories should contain 398 grams of carbohydrate, 112 grams of fat, and 90 grams of protein. In caloric percentage this is stated as carbohydrate 53 per cent, fat 35 per cent, and protein 12 per

cent. In addition to these main constituents it should contain 3,000 to 5,000 International Units of vitamin A, 300 International Units of vitamin B, 250 International Units of vitamin C, and an undetermined amount of vitamin D. The calcium intake should be 90 gram, phosphorus 1.25 grams, and iron 15 to 20 mg. Wolff determined that 16 per cent of the population of the Netherlands and 24 per cent of those suffering from chronic diseases have definitely subnormal vitamin A reserves. Bernheim, from studies of the average diet in America and Waller, from observations of the diets of the 'poorer classes' in England, believe that calcium deficiency is frequent and has serious consequences. A more or less continued hunger and fatigue may be experienced by a diet too high in carbohydrates with insufficient fat. This latter form of unbalanced diet is encountered in many of our women patients. They are continually hungry and are always eating between meals. The cure of this condition consists in a balanced diet with adequate fat content and no indulgence except at regular meal times.

Lack of appetite and atony of the gastrointestinal tract is a well known result of vitamin B deficiency. Individuals with gastrointestinal atony, and particularly those with an achlorhydria, may suffer from vitamin deficiency in spite of an adequate intake. This was first demonstrated by Hurst and Bell, who found that some individuals with subacute combined sclerosis could be cured by the administration of hydrochloric acid.

Vitamin B₁ has recently been so lauded in the daily press that one would believe it to be a new elixir of life, and the appreciation of its true value may suffer some from the extravagant claims made for it. Nevertheless, vitamin B₁ is of value in the relief of anorexia and it also aids in the utilization of food. It is of advantage in promoting the normal growth in infants and essential in the prevention and treatment of some forms of polyneuritis.

Vitamins are only of use, however,

when there is a deficiency, but excessive intake has been shown to be harmless (except for the toxic effects associated with vitamin A sources).

The soluble calcium ions are present in all the body tissues, and have an important function in maintaining the proper permeability of the cell membrane and the normal neuromuscular excitability. Calcium deficiency gives rise to poor appetite and defective nutrition, as well as increased neural and muscular irritability.

Many high strung, nervous patients, who have hyperactive reflexes, crave stimulation. They frequently overindulge in coffee and caffeine-containing beverages, take thyroid or stimulating hydrotherapy. Some of these individuals are benefited by taking calcium although the calcium level in the blood is normal.

Sedatives

Sedatives and hypnotics are among the most frequently prescribed remedies, and pharmaceutical firms keep offering new synthetics and new compounds with bewildering rapidity. Practicing physicians have considerable difficulty in determining the desirable and undesirable effects of these preparations. I will attempt therefore to outline briefly some of the important characteristics of this group.

Bromides were discovered by Balard in 1826 and Graf in 1840 introduced them into medical therapy. Though the pharmacologic action of bromides has been well known for over half a century, I believe that the general practitioner of today is not well informed as to the disadvantages and dangers of this drug.

An investigation in 1928 of 52,000,000 prescriptions issued under the English national health insurance medical scheme demonstrated that about one tenth of these prescriptions contain bromide as the principal ingredient, and that bromide ranked fifth in the list of the most commonly prescribed drugs. It was surpassed only by sodium bicarbonate, ammonium carbonate, sodium salicylate,

and tincture of *nux vomica* Reports of admission to mental hospitals show that bromides cause an appreciable percentage of the toxic psychoses, and there is little question that the bromides prescribed by physicians and consumed in proprietary nostrums produce much chronic ill health

Bromides act by replacing the chlorides of the body and this accounts for the fact that a single dose of 20 to 30 grains will have no effect in a normal individual The principal effect of the bromides is a reduction of the irritability of the motor area of the brain In ordinary doses bromides have almost no sedative action upon the intellectual functions In higher concentrations in the blood they have a slight hypnotic action, but this is due entirely to a blunting of the general sensibilities so that the patient is less distracted by extraneous stimuli

Barbour, Pilkington, and Sargent demonstrated that fatal intoxication occurred in rabbits when bromide replaced 40 per cent of the chlorides These authors believe that it is impossible to accurately correlate symptoms with the bromide levels in the blood, but are of the opinion that quantities less than 100 mg per cent do not cause toxic symptoms Between 100 and 200 mg per cent toxic symptoms are likely to occur in patients with impaired cardiovascular and renal efficiency, and bromide levels above 200 mg per cent produce toxic manifestations in most instances One of the most serious features of bromide administration is the difficulty in ascertaining the proper dose The rate of substitution of bromides for the chlorides depends upon four factors, viz, the bromide intake, the chloride intake, the water intake, the renal efficiency As three of these factors usually are undetermined the actual dose of bromide retained by the patient is unknown Continued administration of bromides has decided dangers if given in doses which have sedative effects and their use should be controlled by frequent determinations of the bromides and chlorides of the blood Bromides should never be administered to elderly patients or to

individuals with arteriosclerosis or impaired kidney function, as under these circumstances excretion is lessened and lower levels of bromide retention produce confusional states and other toxic and psychotic manifestations

Were bromides the only sedative at our disposal there would be reasons for their use, but as we have much more efficient and less dangerous remedies we should welcome the day when bromides are as little used for sedation as chloroform is for anesthesia

In an effort to overcome the toxic effects of the inorganic bromides a number of organic bromine compounds are supplied Brometone and Calbroben or Sabromin are those most frequently used The sedative effects of these drugs does not depend entirely upon the bromine content as they are effective in smaller doses than the alkaline bromides Large doses of Calbroben are said to have injurious effects on the kidneys and none of these preparations are beneficial in convulsive states They are useful as sedatives for individuals who have idiosyncrasies for the barbiturates

Chloral hydrate is a valuable sedative and hypnotic which is not used as frequently as it should be Being very soluble it is readily absorbed and the initial effects are manifest in five to ten minutes, and even sooner with large doses The sleep produced by chloral more nearly resembles physiologic sleep than that induced by any other hypnotic drug While under its influence the patient is easily aroused, and on awakening does not have the lethargy noted with other drugs In doses of 15 to 30 grains there is slight slowing of the pulse and respiration, and lowering of the blood pressure and temperature, but little if any more than is present in normal sleep The principal disadvantages are the pungent taste and gastric irritation which definitely contraindicates its use in gastric ulcer Large doses, viz, over 45 grains, are required to produce sleep of more than three or four hours' duration and to quiet excitement Doses of this magnitude do depress the vasomotor and

respiratory centers and should be used with caution. When chloral is administered during the day as a sedative the possibility of addiction should always be kept in mind. When used as a hypnotic the preferable method is to give an amount which will induce sleep for three or four hours and then to repeat the dose, rather than prescribing a single dose large enough to produce sleep of much longer duration. The average fatal dose is 150 grains and the average anesthetic dose is 50 grains, which gives a wide therapeutic margin.

Paraldehyde has two principal indications. First as a comparatively safe hypnotic in acute mania, delirium tremens and other agitated conditions which would otherwise require dangerously large doses of chloral or barbiturates. Second for the relief of status epilepticus, whether idiopathic, uremic, eclamptic, or the spinal convulsions of strychnine poisoning. In these conditions paraldehyde administered by rectum is a most valuable remedy. It should never be administered intravenously as thromboses are likely to occur. Continued administration as either a sedative or hypnotic is dangerous as personality changes may occur, as well as loss of appetite, dyspepsia, muscular weakness, and tremors. Addiction is easily produced and its results are serious, frequently ending fatally in three or four hours.

In 1903 Emil Fischer and von Mering introduced diethylmalonylurea (or veronal) as a sedative and paved the way for the large group of ureides which comprise the principal sedative and hypnotic agents used at the present time.

There are two principal groups of ureides, the acetylurea derivatives comprising Brom diethyl acetylurea (Carmonal or Adalin), Acetyl brom-diethyl acetylurea (Abasin), and Allyl isopropyl-acetylurea (Sedormid), and the larger malonylurea group which are the barbiturates. There is one valerylurea derivative, viz., Alpha monobrom iso-valerylurea (Bromural).

The acetureides and the valeralurea

derivatives seem to be quite similar in action. It will be seen that three of these preparations contain bromine, but the bromide ion is present in comparatively small quantity and in therapeutic doses can have no appreciable action. These drugs are said to have no notable action upon the gastrointestinal, genitourinary, respiratory, or circulatory systems when used in recommended doses. The principal advantage of these preparations is their mild sedative and hypnotic action without depression or other unpleasant results. Thrombocytopenic purpura occasionally follows the administration of allyl isopropyl-acetylurea (Sedormid)—(Hoffman, Kahn, and Fitzgibbon).

The malonylurea or barbituric acid derivatives are the principal sedative and hypnotic drugs used at the present time. The acids themselves are but slightly soluble in water and their hypnotic properties are about double those of their salts. The salts are readily soluble in water, but these solutions are unstable. Barbiturates are incompatible with chloral hydrate, acids and ammonium salts, and as a rule they should be administered alone.

The principal advantage of this group may be summarized briefly. They are useful in reducing nervousness and promoting sleep, in reducing the frequency of convulsive seizures, and for the production of partial or complete anesthesia. Serious local irritation is not produced, and administration may be by the oral, rectal, or intravenous routes. The effect starts within twenty to thirty minutes on oral administration, in less time when given rectally (when in solution), and immediately when introduced by vein. When used in therapeutic dosage there is no serious disturbance of respiration, circulation, or smooth muscle action, and the after effects are not particularly unpleasant or distressing.

Pharmacological Action of the Barbiturates

Effect on Respiration—The respiratory system is depressed, even by hypnotic doses. The rate may be diminished,

though it is frequently increased, and the excursion is more shallow. In prolonged, deep narcosis, cyanosis frequently occurs and there may be pulmonary edema. Toxic doses produce death either by paralysis of respiration or more frequently by pulmonary edema and subsequent pneumonia. If administered intravenously, unless given slowly, death may be produced by respiratory paralysis even in hypnotic doses. Featherstone stressed the risk of using the barbiturates as basal anesthetics in the presence of catarrhal conditions of the bronchial and upper air passages.

Effect on Circulation—There is a fall in the systolic blood pressure within the first two hours after administration. This is usually unimportant, but severe drops have been reported in individuals with hypertension or following rapid intravenous introduction of the soluble barbiturates. The pulse rate is increased and may be 100 or over in individuals taking barbiturates in the day as well as at night. Dilatation of the peripheral vessels occurs and capillary permeability is increased. The tonus of the heart muscle is decreased. This is sufficient to produce decompensation when patients have taken barbiturates in large doses for extended periods. I have seen alarming symptoms produced by a single dose of sodium amytal in a patient with myocardial insufficiency.

Effects on Blood Chemistry—Blood calcium and phosphorus are decreased. The carbon dioxide tension is increased as a result of the respiratory depression, but the carbon dioxide combining power is unaffected.

Effect on Genitourinary Function—A slight decrease in the urinary output is noted for six to twelve hours but returns to normal later. This fact may be utilized in patients with troublesome nocturia. There is no evidence of renal damage except in cases of fatal poisoning. Willcox reports four cases of fatal urinary suppression following doses of less than 10 grains of nembutal. The smooth musculature of the bladder is relaxed and there is inhibition of voluntary urination.

Large doses of the barbiturates frequently make catheterization necessary. Even small doses of barbiturates may produce impotence through inhibition of the spinal reflexes.

Effects on the Gastrointestinal Tract—The tone of the smooth musculature of the gastrointestinal tract is relaxed. The emptying time of the stomach is delayed and the barbiturates may cause indigestion if administered immediately before or after meals. Postanesthetic nausea and vomiting are diminished when anesthesia is preceded by barbituric medication. It is well known that the barbiturates are the most effective drugs to control the pain and vomiting in the gastric crisis of tabes. Secretions of the gastric and other digestive juices are inhibited. On account of this effect, Zerkow has recommended the use of the barbiturates in the treatment of gastric and duodenal ulcer.

Effects on the Skin and Mucous Membrane—The sensitiveness of the cornea and mucous membrane of the pharynx is diminished. For this reason the barbiturates are of use in reducing coughs produced by pharyngeal irritation. Many types of skin eruptions may be produced by the barbiturates. The most frequent are urticaria, morbilliform or scarletina-form erythema, macular, vesicular, or bullous eruptions. Phenobarbital and some of the other members of this group may produce necrotic ulcers of the mouth and tongue. Poole reports desquamative dermatitis with sloughing, necrosis, edema, and leucocytic infiltration of the bronchial mucosa in fatal barbiturate poisoning. Skin eruptions seem to be most common in individuals with an allergic tendency. Individuals allergic to protein substances are frequently allergic to drugs. The important difference between drug allergy and protein allergy is that drug allergy exists to only one chemical group (for example the phenyl or ethyl group), and not to the entire molecule as is the case with protein sensitization. Therefore a person allergic to one barbiturate may take another derivative with impunity, providing it does not contain the allergic

principle In my experience skin eruptions more frequently result from barbiturates containing the ethyl radical, as barbital, phenobarbital, and maytal, than from those which do not, as for example alurate and dial

Effects on Metabolism—Dameshek, Loman, and Myerson found that sodium amytal produced a rapid and marked fall in basal metabolism The average fall was 26 per cent, with a range from 7 to 70 per cent. The utilization of oxygen and dextrose by the brain is definitely diminished The average fall in temperature was 1.1 F Underhill and Sprunt found a distinct hyperglycemia in rabbits anesthetized with sodium amytal Weiss determined this hyperglycemia to be 80 to 150 per cent in the dog, and 100 to 250 per cent in the cat Metabolism of glycogen in the liver is reduced 50 per cent by sodium amytal anesthesia (Hines, Leese, and Barer) Fontes and Trivolle demonstrated a marked hypoglycemia resulting from the use of allyl isopropyl barbituric acid (alurate)

Effects on the Nervous System—The presence of barbiturates in the nervous system have been demonstrated by many workers In the brain it has been found, particularly in the midbrain and thalamus, which areas are of significance in the production of sleep Barbiturates have been found in the medulla, and particularly in the spinal cord, which doubtless accounts for the changes in the reflexes and ataxia Even small doses of the barbiturates may produce vertigo, muscular inco-ordination, nystagmus, and double vision The pupils are at first somewhat dilated, but in stupor are contracted and less responsive to light The deep reflexes are at first exaggerated but later are diminished or absent Absent ankle jerks are not infrequently found in individuals who take barbiturates continuously In deep narcosis Babinski reflexes may be present, the rectal sphincter may be relaxed, and the diminished bladder tone and absence of the micturition reflex make catheterization necessary When phenyl, ethyl, or

methyl groups are combined in the formation of a barbiturate, the resulting drug has special action on the motor cortex which inhibits cerebral convulsive seizures (phenobarbital, mebaral, and rutilal)

Psychologic effects of small doses of the barbiturates are of considerable interest and importance Sedative doses of the barbiturates, particularly phenobarbital and amytal, give definite changes in the emotional sphere Fear and apprehension are decreased and there is a feeling of serenity and well-being Expression becomes freer and assumes a sense of warmth and even inspiration Self absorption is decreased and a friendly outlook is promoted

Disadvantages, Idiosyncrasies, and Toxic Effects—The pharmacologic response to barbituric medication is rather variable, not alone in different individuals, but in the same individual at separate times The hypnotic stage may be preceded by stimulation and excitement, which in the short action group may proceed from inebriation even to delirium The idiosyncrasies encountered are mainly symptoms of acute or chronic intoxication, but induced by doses which are ordinarily innocuous In my experience the alarming symptoms are most frequently encountered in individuals with myocardial weakness, respiratory difficulties, arteriosclerosis, very high or low blood pressure, or in children Toxic symptoms may be acute or chronic Serious acute symptoms may be a marked fall of temperature and blood pressure, depression of respiration with cyanosis and pulmonary edema, or respiratory paralysis Chronic poisoning occurs when the longer acting barbiturates are administered at too frequent intervals The most prominent manifestations of chronic poisoning are mental symptoms, which may be excessive fatigue, debility, and retardation, impairment of ethical and moral appreciation, with muscular inco-ordination and speech defects, epileptiform convulsions may occur, or an acute toxic psychosis with confusion, hallucinations, and excitement.

Pathologic Changes in Fatal Cases — The depression of cell function caused by the lipolytic narcotics is believed to result from alterations in the colloidal systems of the cell surface. In narcotic concentration these alterations result in a definite decrease in the permeability of the cell membrane. Toxic concentrations of narcotic drugs increase the permeability of the cell membrane and thus alter the cell substance which may become disorganized, injured, or killed. The pathologic findings in fatal cases of barbiturate poisoning are in general what would be expected of an agent which causes an increased permeability of the cell membrane and destruction of the cell protoplasm. These findings as reported are cloudy swelling of the parenchymatous organs with perivascular hemorrhages. Small hemorrhages are found particularly in the brain, heart, lungs, kidneys, liver, and the submucosa of the gastrointestinal tract. The cells of the cerebral cortex, brain stem, and cerebellum show an absence of Nissl bodies and other evidences of disintegration including rupture of the cell membrane and the presence of granular products of degeneration. Congestion of the lungs is a constant finding and usually there are evidences of bronchopneumonia.

A full description of the individual properties of each of the barbiturate preparations is not within the scope of this paper, but a brief statement of some of the little emphasized advantages or disadvantages may be given.

Iso-propyl-ethyl barbituric acid (Ipral) is the least hypnotic of the barbiturates, and complete recovery from the sedative effects is delayed longer than any other member of this group. The anesthetic dose is about 80 per cent of the fatal dose, and continued administration of small doses frequently produces stuttering.

Isoamyl-ethyl barbituric acid (Amytal) causes increased muscle tension and has the tendency to produce tremor in

normal individuals. When administered to patients with paralysis agitans it lessens the tremor of the disease by greatly increasing the rigidity. This rigidity may be so marked that the patients are rendered completely helpless.

Cyclo-hexyl-ethyl barbituric acid (Cyclobarbital Phanadorn) is an effective hypnotic, though somewhat variable in action. It has less depressing effects upon respiration and has the least tendency of any of the barbiturates to produce muscular rigidity and trembling.

The sodium salt of normal hexyl-ethyl barbituric acid (Ortal Sodium, Hebaral Sodium) has very little hypnotic effect in recommended dosage but it is a good euphoric sedative.

Diallyl barbituric acid (Dial) has pronounced toxic effects. Transient vertigo and nausea are frequent. Tolerance rapidly develops but there is much individual difference in tolerance and action. Toxic doses cause muscular inco-ordination and trembling, convulsions, and delirium.

Sodium propyl-methyl-carbinyl-allyl barbiturate (Seconal) is an excellent short action hypnotic. The sleep induced by $1\frac{1}{2}$ to 3 grains of this drug is of very brief duration, but there is no depression of other unpleasant after-effect. Tolerance is not easily acquired.

The therapeutic breadth or therapeutic index is the figure obtained by dividing the minimal fatal dose by the minimal anesthetic dose. The results of these experiments vary somewhat, depending upon the animals used and on other conditions. Nevertheless, these figures give some idea as to the comparative safety or dangers of these preparations. A list of the therapeutic indices of the principal barbiturates in order of decreasing toxicity is as follows.

| Chemical name | Trade name | Index |
|--|-------------------------------|-------|
| Isopropyl-ethyl barbituric acid | Ipral | 1 22 |
| Phenyl-ethyl barbituric acid | Phenobarbital, Luminal | 1 5 |
| Diethyl barbituric acid | Barbital Veronal | 1 63 |
| Sodium ethyl (1 methyl butyl) barbiturate | Phenobarbital Sodium Nembutal | 1 7 |
| Sodium isoamyl-ethyl barbiturate | Amytal Sodium | 1 79 |
| Sodium salt of secondary isobutyltetra brom propynal barbituric acid | Pernoston | 2 1 |
| N methyl-ethyl phenyl barbituric acid | Mebaral Prominal | 2 3 |
| N butyl-ethyl barbituric acid | Neonal Soneryl | 2 3 |
| Allyl isopropyl barbituric acid | Alurate | 2 43 |
| Cyclo-hexyl-ethyl barbituric acid | Cyclobarbital Phanadorn | 2 44 |
| Isoamyl-ethyl barbituric acid | Amytal | 2 45 |
| Diallyl barbituric acid | Dial | 2 5 |
| Sodium propyl methyl-carbinyl allyl barbiturate | Seconal | 2 7 |
| Sodium N methyl-cyclo-hexenyl barbituric acid | Cyclural Evipal Evipan | 3 3 |
| Sodium hexyl-ethyl barbiturate | Ortal Sod Hebaral Sod | 4 0 |

A glance at these figures shows that the minimal anesthetic dose of the first five of these preparations is uncomfortably close to the minimal fatal dose

In classifying the barbiturates I would like to divide them into three groups

1 Barbiturates useful as sedatives

Phenyl-ethyl barbituric acid (Phenobarbital) in doses not exceeding 3 grains daily

N methyl-ethyl phenyl barbituric acid (Mebaral) in doses not exceeding 6 grains daily

Allyl isopropyl barbituric acid (Alurate)

Sodium hexyl-ethyl barbituric acid (Ortal Sodium)

2 Barbiturates useful as hypnotics

Isoamyl-ethyl barbituric acid and the sodium salt (Amytal and Sodium Amytal)

Cyclo-hexyl-ethyl barbituric acid (Cyclobarbital)

Sod-ethyl (1 methyl butyl) barbiturate (Phenobarbital Sod Nembutal)

Sodium propyl methyl-carbinyl-allyl barbiturate (Seconal)

N methyl-cyclo-hexenyl barbituric acid (Cyclural Evipal Evipan)

Isobutyl-allyl barbituric acid (Sandoptal)

3 Preparations not recommended for ordinary use because of prolonged action or toxic effects

Barbiturates combined with amidopyrine (Allonal, Paralga, Dormalgin)

Diethyl barbituric acid and its sodium salt (Barbital Veronal Medinal)

Diallyl barbituric acid (Dial)

Isopropyl-ethyl barbituric acid (Ipral)

Sodium salt of secondary isobutyl tetra brom propynal barbituric acid (Pernoston)

Diethyl barbituric acid and allyl isopropyl barbituric acid (Somnifene)

In conclusion I wish to plead for the discontinuance of the use of the inorganic bromides except in convulsive states. As usually prescribed bromides have little or no beneficial action and may cause serious ill health. Chloral hydrate is an excellent sedative and hypnotic and deserves more frequent use. The barbiturates are valuable sedative and hypnotic drugs, but their use should be limited and their indications and toxic effects thoroughly understood. Anesthetic doses are dangerous and require the careful supervision and precautions used in general anesthesia.

Discussion

HAROLD T HYMAN, M D, New York City — Dr Howe has clearly delineated a most comprehensive and practical discussion of the use of the tonic and sedative drugs in neurologic practice. There are a few variants that might merit a word of discussion

In the use of thyroid extract as a tonic, I am insistent on estimations of the basal metabolic rate. I do not prescribe thyroid extract, except in rare instances, unless the rate is depressed. I insist upon check-up rates to alter to a maintenance dosage that amount which is necessary to correct the obviously low rate. Only in this way, may adequate dosage be insured and toxic symptoms prevented. Apart from the classically obese flabby hypothyroid group, there is a second viscerotonic asthenic group, strikingly underweight, who paradoxically not infrequently has a low basal metabolic rate. Such patients may also have amenorrhea, oliguria, and sterility, and are sometimes referred to the internist by the gynecologist. These patients, I believe, may best be classified as forme fruste of pituitary cachexia. The basal metabolic rate is often done with the expectation of finding that it will be high and, to our great amazement, it will be found significantly low, and thyroid extract may be prescribed with tonic and adjuvant effect.

I can also confirm what Dr Howe has said about the use of hypophosphites, glycerophosphates, glycerophosphates, and arsenicals such as cacodylate of soda. Pharmacologically, they are completely inert and may well be classified as useless drugs. In the early years of my practice, I prescribed them through sheer despair and as a placebo. While the tonic effect of these drugs is by no means constant, it is certainly commented upon with sufficient frequency by patients so that I gain the impression that there must be some beneficial metabolic alteration that occurs of which we are still ignorant.

The use of suprarenal cortex in any form is completely disappointing, as Dr Howe has re-

ported, but I can confirm his favorable results, particularly in the underweight asthenic patient, from small doses of insulin.

Personally, I never use strychnine, caffeine, or benzedrine sulfate as tonics. In point of fact, I am opposed to their use, for I think that this type of artificial stimulation is a mirage and holds much greater potential for damage than benefit.

The use of the balanced diet with particular emphasis on high vitamin intake, both in the diet and artificially, I can confirm with great vigor. This is particularly true in alcoholics and those foolish females, of whom we all see our share, whose goal with regard to their weight and figure seems to be the approach to the appearance of tuberculous cachexia.

To the tonic preparations that Dr Howe has mentioned, I would add the much more potent tonic measures of exercise either by walking, dancing, the indulgence in sports, or conducted calisthenics, particularly in flabby and overweight individuals.

For the tense, high-strung individual who is enmeshed in situational difficulties, I am a great believer in the old fashioned Wier-Mitchell rest cure, followed by a regimen including physical activity.

I am also a great advocate of the tonic effect of whisky or a cocktail, particularly for older patients, taken some time in the late afternoon.

I have been very much impressed with the tonic effect of ultraviolet radiation, which is now available to patients in their own homes with reasonably low priced sources of true ultraviolet radiation.

With regard to the sedatives, I can echo what Dr Howe has said concerning bromides. I doubt whether I ever prescribe a bromide prescription, mainly because of the great frequency of dermatitis medicamentosa.

Like Dr Howe, I believe that there is still no sedative or hypnotic to compare with chloral hydrate, though I must confess that I use much lesser dosage than does Dr Howe.

Paraldehyde is also a great favorite of mine. It is not used nearly as frequently as it should be used. I believe it is superior in every way to the more widely publicized and expensive preparations such as avertin. I have no fears about its intravenous injection, particularly in the maniacal states that are associated with ominous medical conditions such as pneumonia, nephritis, eclampsia, and the various cardiac psychoses. While nothing can be done about the odor of the drug, its taste may be well and conveniently disguised in ice-cold beer. I have never seen a paraldehyde addict.

Concerning the barbiturates, I have very defi-

nite principles. I never prescribe veronal because of its tendency to addiction. I completely avoid sedormid because of three instances of thrombocytopenic purpura with which I am familiar. I avoid all of the barbiturates except those which have been approved by the Council of the American Medical Association, for I think we should firmly support the Council in its attitude toward these preparations. I think that the hy-effects on circulation, metabolism etc. are purely academic in interest except in instances of massive poisoning. I make every effort to

avoid the prescription of any of the barbiturates always trying sedative measures that do not involve the use of drugs. These measures would include exercise, simple hydrotherapy in the ordinary bathtub by means of a luke-warm bath or a shock bath, or a pine needle bath, the use of warm milk at bed time, a quieting massage or the soothing effects of heat in the form of a hot water bottle or an electric pad. These measures, filling a simple chloral preparation in increasing dosage, is probably the least noxious and most effectual prescription.

DOCTORS SAVE MORE MEN IN MODERN WARS

Another great war in Europe would produce fewer deaths from wounds, fewer maiming in injuries and less disease per man power than in any major conflict of the world's history, military medical experts say.

Despite improvements in the art of killing during the past twenty years, modern medical practice in most countries has advanced even faster, they declare, and physicians and surgeons are better equipped than ever before to prevent illness and care for wounded men.

Among recent advances which would protect the soldier against sickness and care for him when wounded are new vaccines and serums to prevent or aid in curing such diseases as tetanus, poisoning, scarlet fever, diphtheria, and measles, knowledge of food needs to prevent the deficiency diseases, such as scurvy and beriberi, new drugs and anesthetics, improved surgical techniques, particularly in repairing bone and head injuries and in plastic surgery, and fast automobiles and airplane ambulances.

Major Isaac J. Frisch, medical corps officer with the Illinois National Guard, declared in an article in *The Military Surgeon*, official journal of the Association of Military Surgeons, that medical science has in its grasp the power to control and crush the diseases which in former wars decimated armies and populations.

Smallpox, typhoid, typhus, dysentery, cholera, malaria, and scurvy can be controlled, he added, as well as many other diseases of the camp and battlefield.

Dr. Charles R. Reynolds, surgeon general of the army, added that preventive medicine is our great field. Through advances in medicine it is now possible to salvage more human beings in wartime than ever before.

The new health protective measures would keep more effective men in the field with a lower cost in maintaining hospital and medical facilities behind the lines and a lessened drain on the civilian population for fresh troops. During the World War approximately eighty per cent of all American injured men were returned to duty.

Orthopedic surgery to repair broken bones without malformation has made rapid strides, indicating fewer permanent injuries, and many operations on the heart and brain, previously considered impossible, have proved successful. Many such procedures, including plastic surgery, received their greatest impetus during the World War, army surgeons declared, and have resulted in the saving of thousands of lives in peacetime.

One of the few advantages of war is the rapid development of medicine and surgery during the conflict and immediately afterward, government surgeons agreed.

RED HAIR AND ANESTHESIA

Speaking at the British Medical Association conference, Dr. C. J. M. Dawkins (London) asked why it was more difficult to maintain a smooth anesthesia with patients with red hair than with those with fair hair or dark hair.

On seeing a patient with red hair come into the gas room, one instinctively prepared for difficulty in maintaining a smooth anesthesia, and this fact was borne out by investigations, as

0.13 per cent of red haired persons required restraint, compared with only 0.05 per cent of fair haired patients and 0.04 per cent of dark haired patients.

Turning to induction time, it was found that fair haired people were induced on an average in fifty-two seconds, dark haired people in sixty-two seconds, and red haired people in sixty-eight seconds.

BENZEDRINE SULFATE THERAPY

The Present Status

EDWARD C REIFENSTEIN, JR, A B, M D and EUGENE DAVIDOFF, A B, M D,
Syracuse

From the Department of Psychiatry and the Department of Medicine, Syracuse University College of Medicine, and from the Syracuse Psychopathic Hospital, Dr Harry A Steckel, Director

We are indebted to Mr Theodore B Wallace of the Smith, Kline and French Laboratories (Philadelphia, Pa.) for the benzedrine sulfate employed in our own studies

DURING the past two years, benzedrine sulfate—(beta-phenylisopropylamine sulfate) an epinephrine-series derivative which stimulates the central as well as the sympathetic nervous system—has been presented to the medical profession as a therapeutic agent for a variety of physical and mental conditions. A review of the status of the drug is essential in order to (1) clarify the extensive literature which has accumulated, (2) re-emphasize the occurrence of untoward effects, a danger to which we have previously directed attention,¹ (3) discourage physicians from administering the drug indiscriminately for symptomatic relief without adequate supervision or thorough investigation, and (4) particularly stress the fact that many of the reports, still experimental in nature, are unconfirmed and controversial.

Widely disseminated newspaper misinterpretation of such data unfortunately has led to promiscuous and dangerous self-medication by the misinformed layman. Such publicity and its pernicious concomitants cannot be condemned too strongly.

PHARMACOLOGY

A review of the pharmacology of benzedrine sulfate, particularly in regard to the conflicting data, is a necessary prerequisite for understanding, defining, and limiting the therapeutic application of this pseudo-sympathomimetic drug.

I Effect on Nervous System and Mental Functions

(a) *Neurological and Mental Status*
In 1933, Alles² observed that benzedrine compounds had a tendency to awaken animals from barbitol anesthesia. Shortly after, an insomnia-producing effect was noted in man by Alles and Prinzmetal,³ and in 1935, Prinzmetal and Bloomberg⁴ utilized this effect in the treatment of narcolepsy. Since that time the stimulating action on the central nervous system has been demonstrated by many observers.^{1, 5-24}

In general, the major effects on the mental state of normal individuals include increase in alertness, initiative, general efficiency, motor and speech activity and irritation, elevation of mood, decrease in fatigue, and insomnia. In addition, we have observed¹ with some regularity paradoxical effects such as increase in fatigue, depression, agitation, dullness, transitory delirium, dizziness, and vasomotor reactions. In general, increase in motor and speech activity was more pronounced than elevation of mood. Bradley¹⁶ found that the drug had the apparently paradoxical effect of subduing children with aggressive behavior traits. From a study of the toxic effects produced by prolonged continuous inhalation, Waud concluded²⁵ that the stimulation of the central nervous system is striking but relatively temporary, and is always followed by marked fatigue and mental depression when toxic doses of benzedrine are absorbed.

(b) *Intelligence tests* Objective stud-

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, May 10, 1938*

ies of mental performance were first reported by Sargent and Blackburn²² who found an average increase of approximately eight per cent in intelligence test ratings following benzedrine sulfate. These findings have been confirmed by Molitch and associates^{27, 28} and Bradley.¹⁸ The improved responses were thought to be due to relief from unpleasant somatic sensations, increased mental activity, and increased decisiveness, although headache or indifference unfavorably influenced some of the scores. The studies of Barmack²⁹ seem to indicate that benzedrine sulfate increases the inclination rather than the ability to do work. In our experience, persons with inherently low mental levels showed little alteration in intelligence scores after the drug, although patients with early toxic or infectious psychoses were apt to increase their rating as the abnormal mental state cleared.

II Cardiovascular System

(a) *Blood Pressure* Most observers admit that benzedrine sulfate in sufficient dosage by mouth usually produces elevation of the systolic and the diastolic blood pressure. Along with Anderson and Scott³⁰ we have called attention³¹ to the diastolic elevations or depressions. Some observers feel that little effect on the blood pressure is noted with doses of less than 20 mg. However, we have witnessed significant variations following doses of 10 mg. and less. In one patient the levels rose from 142/92 to 210/120 one hour after 10 mg. In addition, we have frequently noted paradoxical falls in blood pressure for example, from 125/88 to 98/60. We have found unpredictable increase or decrease in both the systolic and diastolic levels occurring singly or in combination. As we have previously pointed out,¹ the blood pressure effect is independent of the mental stimulation, and therefore blood pressure change is not a criterion for estimating the psychologic response. Within limits, increasing doses produce greater variations in blood pressure. The pressor effect appears not infrequently to be

diminished following several days of repeated doses. Storz and Kirk¹⁸ found a fall in blood pressure with 10 mg. and a rise with 20 mg. After continuous inhalation of benzedrine for four to six hours, Waud²⁴ noted orthostatic hypotension on several occasions. The influence of posture and exercise on the variations in blood pressure following benzedrine sulfate has not been thoroughly investigated.

With subcutaneous administration, Myerson, Loman, and Dameshek³² found a rise in the systolic pressure in all but one of eighteen patients. There was a noncommensurate increase in the diastolic level of the blood pressure.

We have given benzedrine sulfate intravenously³³⁻³⁷ to a number of patients. Immediately following 10 mg. doses we frequently observe a fluctuation of 10 to 30 mm. of mercury in the systolic pressure which makes accurate determination of the level difficult. In general, 20 to 30 mg. of benzedrine sulfate raised the systolic level 30 to 50 mm. with a 20 to 30 mm. increase in the diastolic level. The maximum elevation was usually obtained within thirty to sixty minutes. In one case, 10 mg. of the drug elevated the blood pressure from 110/60 to 200/100 in five minutes. In two patients who had received 1 Gm. of sodium amytal intravenously, 105 and 130 mg. of benzedrine sulfate intravenously caused the following variations: 90/64 to 220/114 and 70/50 to 188/102. In some cases there was a fall after the intravenous administration. We have previously reported³³ that benzedrine sulfate intravenously in 10 mg. doses restores to preanesthesia levels, blood pressures which have been depressed by 0.5 Gm. of sodium amytal intravenously. One patient in collapse from sodium amytal with a blood pressure of 50/0 experienced an immediate rise to 140/90 following 10 mg. of benzedrine sulfate intravenously.

(b) *Pulse*—Several observers have noted that benzedrine sulfate makes the pulse labile and easily influenced by exertion. This may account for many of the increased pulse rates reported fol-

lowing oral administration of the drug, where presumably the patients were up and about. However, inconsistently, even in patients at rest we have witnessed increases in pulse rate as well as slow rates in patients who were active. Following subcutaneous³² and intravenous administration³³⁻³⁷ of the drug in patients who are kept quiet in bed, the pulse rate frequently falls. Elevation of the pulse rate is prone to occur in patients who exhibit little alteration of the blood pressure. Following the inhalation of toxic doses of the drug Waud²⁵ found a bounding pulse at rest and a weak, thready pulse on exertion, while slight exercise produced marked tachycardia. Bradycardia was observed once. The influence of posture and exercise on the variations in pulse rate has not been thoroughly investigated.

(c) *Heart*—Following oral administration of benzedrine sulfate, observers have occasionally noted sinus arrhythmia, extrasystoles, paroxysmal tachycardia, palpation, and bradycardia. Anderson and Scott³⁰ mentioned six cases with cardiovascular reaction—four had precordial pain, one had extrasystoles, and one had collapse with precordial pain, a drop of thirty beats in pulse rate, and a one to four heart block. Following subcutaneous administration of the drug, Dameshek, Loman, and Myerson³⁸ noted very little effect on the electrocardiogram in eight patients except for slight increase or decrease in the size of the T wave.

III Gastrointestinal System

The controversial nature of the reports on the action of benzedrine sulfate is nowhere more evident than in those relating to the gastrointestinal system.

(a) *Stomach*—Reports on the effect of benzedrine sulfate on the human stomach as observed by roentgenographic study have been published by Myerson and Ritvo,³⁹ Smith and Chamberlin,⁴⁰ and Van Liere and Sleeth.⁴¹ There is general agreement that benzedrine sulfate decreases peristaltic activity of the stomach in hypertonic states, has little

effect on it in normal tonic states, and increases it in hypotonic states. Myerson and Ritvo³⁹ claim that "the stomach actually empties more rapidly than normally under the influence of the drug." Smith and Chamberlin⁴⁰ and Van Liere and Sleeth,⁴¹ however, report that the stomach empties less rapidly than normally. Beyer and Meek⁴² correlate these opposing statements by animal fluoroscopic studies which revealed a more rapid initial emptying with a delayed final emptying of the stomach. Myerson and Ritvo state that the drug decreases the tonus in a hypertonic stomach, but has little if any effect on a stomach with normal tone or hypotonicity. Van Liere and Sleeth agree that benzedrine sulfate is capable of relaxing gastric musculature. Beyer and Meek in animals found that increased tonus and rate of activity appeared in about eight minutes, but that inhibition of activity even to cessation with or without slight loss of tonus took place within forty minutes. Myerson and Ritvo claim that the drug produces relaxation of the pyloric sphincter, but Van Liere and Sleeth do not believe that this has been demonstrated to date, pointing out in passing the uncertainty of the action of epinephrine on the pylorus. Ritvo⁴³ states that the use of atropine and benzedrine together in the gastrointestinal tract was distinctly less effective than benzedrine alone.

Myerson, Rinkel, and Dameshek⁴⁴ found that benzedrine sulfate either slightly diminished or did not affect the amount of gastric juice, but definitely and regularly increased the free hydrochloric acid and the pepsinogenic activity of the gastric secretion. Smith and Chamberlin⁴⁰ reported that the drug increased gastric acidity to a slight extent in normal persons but to an insignificant degree in patients with spastic conditions of the stomach and the duodenum.

(b) *Duodenum, Small Intestine, and Colon*—Myerson and Ritvo³⁹ and Smith and Chamberlin⁴⁰ agree that benzedrine sulfate relaxes the smooth muscle of the duodenum, the small intestine, and the colon. However, the latter observers

noted a moderate amount of to-and fro churning and an occasional peristaltic rush in the proximal small intestine. Van Liere and Sleeth⁴¹ postulate that the peristaltic activity of the small intestine might be lessened, at times sufficiently to produce intestinal stasis. Starr⁴² reported that increased peristaltic activity in the terminal small intestine produced by barium ceased after the injection of benzedrine sulfate subcutaneously. In contrast to these findings, Beyer and Meek,⁴² in animals, were unable to demonstrate any constant effect on the intestinal tract of benzedrine orally, subcutaneously, intravenously, or by direct infusion into intestinal fistulae.

(c) *Gallbladder*—Schube, Ritvo, Myerson, and Lambert,⁴⁴ as a result of fluoroscopic studies, reported that benzedrine sulfate did not cause the gallbladder to contract. The organ emptied normally in response to a fat meal given thirty minutes after the administration of the drug, but failed to evacuate when the fat meal was given two hours after the benzedrine sulfate. They implied a delayed effect on the gallbladder. Smith and Chamberlin⁴⁵ employing biliary drainage confirmed these observations except that they did not study the effect of a fat meal two hours after the drug had been administered. In cats, Flexnor, Bruger, and Wright⁴⁷ reported that benzedrine sulfate produced immediate relaxation in gall bladders that previously had been contracted by acetyl beta methyl-choline chloride.

(d) *Clinical Observations*—Along with other observers, we have noted the following clinical effects of benzedrine sulfate on the gastrointestinal tract: anorexia, nausea, belching, abdominal cramps, flatulence, increase or decrease in frequency of bowel action, and increase or decrease in amount of stool. We have been particularly impressed by the unpredictable appearance of diarrhea or constipation in our patients. Vomiting¹⁶ and spasm of the rectal sphincter⁴⁸ have been reported by others. Jaundice appearing during the administration of benzedrine sulfate was recorded by Donley.¹⁸

IV Genitourinary System

(a) *Urinary Tract*—We have noted an increase or a decrease in the frequency of urination with either an increase or a decrease in the total daily urinary output after benzedrine sulfate administration. Other observers have reported dysuria,⁹ difficulty in initiating micturition,⁴⁹ and aggravation of pre-existing frequency and urgency.⁴⁹ Myerson⁴⁰ has stated that benzedrine sulfate relaxes the urinary bladder. Waud²⁵ reported that toxic doses of the drug by inhalation produced marked shrinkage of the external urethra, immediate diuresis of 500 to 2,000 cc. in 4 to 6 hours, and moderate suppression of urine after 8 hours for one day.

(b) *Genital Tract*—Ulrich et al.⁶ observed an additional menstrual period in an adolescent girl following the daily administration of 50 mg of the drug. Solomon et al.¹⁸ reported an increase in sexual potency in two male patients. After toxic doses by inhalation, Waud²⁵ found increased libido for a short period followed by decreased libido for two hours to four days.

V Upper Respiratory Tract

Inhalation of the vapor of benzedrine has been reported to produce shrinkage of the mucous membranes and diminution of nasal secretion.⁵¹⁻⁵⁴ Toxic doses have produced paradoxical effects.²⁵

Along with other investigators we have observed that internal administration of benzedrine sulfate may cause increase or decrease of nasal secretion, parching of the mouth and throat or increased salivation, and a peculiar "metallic" taste.

VI. Respiration

All investigators are agreed that benzedrine sulfate in the usual therapeutic doses has little effect on respiration. Following toxic doses by inhalation, Waud²⁵ observed dyspnea, foamy sputum, emphysema, and moist râles in the lungs for one to three days. In animals some investigators^{3,48} have found stimulation of respiration by the drug while others have observed no effect.⁶ We have

found that the depression of respiration produced by large doses of sodium amytal is little if at all influenced by benzedrine sulfate

VII. Bronchi

Although a definite but poor bronchodilator effect from benzedrine sulfate has been observed in animals,⁶⁷⁻⁷⁰ no studies have been reported on this action in the human subject

VIII Eye

Myerson and Thau⁷¹ have reported that solutions of benzedrine sulfate of $\frac{1}{8}$ to one per cent instilled in the eye produced a dilation to complete mydriasis in from fifteen to thirty minutes, and an increase of 2 to 4 mm in intra-ocular tension. Atropine and its derivatives appear synergistic to benzedrine sulfate when instilled in the eye,⁷²⁻⁷⁶ producing cycloplegia with reduced doses which is rapidly induced in one-half to one hour and quickly dissipated in five to seven hours. Myerson and Thau^{71,76} also reported that benzedrine solution caused the reappearance of the reaction to light in Argyll-Robertson pupils.

Internal administration of benzedrine sulfate has been found by us to produce injection of the conjunctivae and dilation of the pupils. Blurred vision has been mentioned by others.²³ In postencephalitic Parkinsonism, oculogyric crises have been reported to disappear, or to be reduced in severity and number.^{15,77-79}

IX Weight

During the administration of benzedrine sulfate we have frequently noted an initial moderate loss of weight in some subjects, and after the drug was discontinued, a marked gain in weight in others. Loss of weight has been observed by Shapiro,¹⁰ Nathanson,⁹ Schube et al.⁸⁰ and Ulrich.⁴⁹ The loss has variously been explained as due to anorexia and lessened appetite, increase in physical activity, moderate increase in basal metabolic rate and loss of fluid through increased sweating, urination, and defecation. Ehrlich and Krumbhaar⁸¹ found

that rats receiving 20 mg or less of the drug daily stopped growing for three weeks and then began to grow again, while those receiving larger doses continued to lose weight. They demonstrated a marked diminution in food intake in these animals. Wilbur et al.^{11,12} however, observed loss of weight in only two of twenty-three patients with "chronic exhaustion." Lesses and Myerson⁸² reported considerable decrease of weight in sixteen of seventeen patients treated over periods of six to twenty-five weeks with a diet of 1,400 calories and benzedrine sulfate. Two patients lost forty-eight and fifty-four pounds, respectively, and five others more than twenty pounds. However, most of the patients were obese psychoneurotic individuals. The loss was attributed to the reduced food intake and the amelioration by benzedrine of the desire to overeat. Waud²⁵ reported that toxic doses by inhalation produced an average loss of ten to fourteen pounds in three to four days, after which the weight was quickly restored to normal.

X Cellular Elements of the Blood

In eleven of fifteen patients, Myerson et al.³² found an increase of at least one million in the total number of erythrocytes per cubic mm within two hours after a subcutaneous injection of 40 mg of benzedrine sulfate. In one patient the count reached nearly eleven million. They also observed an increase to as much as four times the original level in the leukocyte count, particularly in the polymorphonuclear cells. No immature cells were found. They assumed these alterations to be due to an effect on the hematopoietic reservoirs, such as the spleen, rather than to stimulation of the bone-marrow. We have been unable to produce such striking alterations in the blood picture with doses as high as 30 mg daily, orally or intravenously. Donley¹⁸ and Bradley¹⁶ also observed no significant changes in the blood. Davies³³ reported the occurrence of acute aplastic anemia following 190 mg of the drug by mouth taken in a period of nineteen days.

Schube, Raskin, and Campbell¹⁴ made studies of the blood in a series of patients who six months previously had been given the drug orally or subcutaneously for a considerable period, and they concluded that in these cases benzedrine sulfate produced no permanent alterations in the hematopoietic system

XI Chemical Elements of the Blood

Along with Peoples and Guttman,⁸ Myerson et al.,¹¹ and Donley,¹² we have observed no alterations in the blood sugar level following benzedrine sulfate. However, Storz and Kirk,¹³ using the German benzedrine compound, found a fifteen to twenty per cent increase in the sugar level two to four hours after administration. We noted no change in the nonprotein nitrogen level of the blood in ten cases.

XII Basal Metabolic Rate

We have observed a transitory increase in the basal metabolic rate in some cases following benzedrine sulfate, but have noted frequently a decrease in the rate, and have not been convinced that there is a consistent variation. In our experience an elevated rate was more apt to obtain in patients with originally low levels. Similar observations on three cases have been reported by Lagen, Soley, and Leake.¹⁵ Ulrich¹⁶ has found a temporary moderate increase in rate but no permanent alteration even after prolonged use. A moderate elevation of rate which was progressively increased by fractional oral doses up to 40 mg and which reached maximum about two hours after administration was reported by Molitch and Poliakoff.¹⁷ The alteration varied between three and fourteen per cent. Myerson et al.,¹¹ Nathanson,⁹ and Donley¹² observed no change in the basal level following the drug.

XIII. Miscellaneous

(a) *Spinal Fluid*—Myerson et al.¹¹ recorded a moderate rise in the spinal fluid pressure coincident with the rise in blood pressure in fourteen cases.

(b) *Skin*—We have observed that

benzedrine sulfate may produce the following effects on the skin: flushing of the face, urticaria, pustular eruption, cutis anserina, sensations of warmth, excessive sweating with a peculiar odor to perspiration, greasiness, dermatographia, circumoral pallor, cyanosis, dryness, coldness and clamminess of the hands, and occasional paresthesias. Similar effects have been reported by others.

(c) *Reflexes*—We have noted that the deep reflexes are occasionally increased following benzedrine sulfate particularly in patients who exhibit tremulousness.

(d) *Urine and Stool*—Except for increases or decreases in amount of urine or of stool we have found no pathological variations in the excreta. Similar observations have been reported by others. Following toxic doses by inhalation Waud¹⁸ observed no abnormal findings in the urine.

(e) *Temperature*—We have noticed a variation of approximately one degree in the temperature of most patients receiving benzedrine sulfate and have observed that patients with initial subnormal levels tend to have an increase. Storz and Kirk¹³ recorded a rise in temperature of one degree in three of fourteen cases.

(f) *Carotid Sinus*—Robinson^{17,18} has reported that benzedrine sulfate will diminish or eliminate induced and spontaneous syncope due to a hyperactive carotid sinus reflex.

(g) *Constitution and Habitus*—Asthenic individuals appeared to us to be more sensitive to benzedrine sulfate than pyknic types. We have made no effort to correlate the asthenic habitus with the so-called vagotonic states because we are impressed by the amphotonic nature of the reactions of most individuals. We have noted that persons with vasomotor instability are more sensitive to the drug, particularly those with low and labile blood pressure. Peoples and Guttman⁸ and Shapiro¹⁹ have reported similar observations. We are not able to agree with Guttman and Sargent¹⁴ that persons with cyclothymic tendencies have the most constant favorable reaction to the drug. Hill²¹ stated that benzedrine sulfate had a

greater beneficial effect in those cases of seasickness in which there were signs of excessive vagus activity Woolley³² reported no difference in the response of vagotonic and sympathetictonic patients

(h) *Enuresis*—In boys who had nocturnal enuresis, Molitch and Poliakoff³⁰ found benzedrine sulfate of value in decreasing the depth of the slumber, thus increasing the response to the call to urination

XIV Posology

(a) *Onset and Duration of Effect, and Dosage*—In general, following oral administration of benzedrine sulfate in doses of 10 to 30 mg effects of the drug begin to appear in from forty-five minutes to two hours When the drug is injected subcutaneously, the pressor response is usually apparent in five minutes With intravenous administration, responses appear at times immediately or within five minutes

The maximum response of a given individual dose depends to some extent upon the particular pharmacologic reaction evaluated, but, in general, the maximum blood pressure response from oral administration appears in two to four hours Following subcutaneous injection, Myerson³² reported that the blood pressure reached the highest level in eleven to eighty-five minutes We have observed maximal alterations in blood pressure within thirty to sixty minutes following intravenous administration

Following oral administration of a single dose, blood pressure variations were usually found to disappear in four to eight hours Subjective reactions such as insomnia may persist for seven to sixteen hours after administration Blood pressure elevations produced by subcutaneous injection were found to disappear in one and one-half to eight hours We have found that blood pressure elevations produced by intravenous administration of the drug have returned to normal in eighty-five minutes to seven hours

A number of patients have tolerated large doses of the drug We have given a patient 200 mg orally in one day without untoward effects Carlisle and Hecker³⁰ gave four patients 60 mg of the drug by mouth daily for sixty-five days (3,900 mg) without untoward effects Patients with orthostatic hypotension have received 150 mg of the drug daily for six months³¹ Subcutaneously Piness, Miller, and Alles³² and Myerson³² injected 50 mg without harm We have injected intravenously 40 mg as a single dose and a total of 105 and 130 mg over a period of an hour in two patients without alarming reaction

In certain types of illness, benzedrine sulfate has continued to prove effective over long periods of time Narcoleptics are continuing to receive benefit after a period of more than three years of daily administration In orthostatic hypotension the drug has remained effective for over six months³¹ The unpleasant effects disappeared after a few days in some cases, but appeared to accumulate in others Wilbur et al.^{11,12} have observed that certain patients develop tolerance to the drug and therefore suggested intermittent administration to prevent this Some observers^{11,12,22} feel that the response of the patient on the initial day of treatment is an index of the effect that can be expected from the drug However, we have observed cases of mental illness in which the response to prolonged administration could not have been predicted on the first days of medication This has made us feel that a delayed response to the drug occurs Donley¹⁸ noted the sudden development of marked hypertension and jaundice after two weeks of uneventful administration

The determination of the minimal effective dose of benzedrine sulfate depends upon what criterion is used for estimating the response to the drug We have found that definite blood pressure variations can be produced by doses of 5 mg and in some cases by doses of 2 mg However, many observers feel that doses of 10 to 20 mg are necessary

to produce blood pressure alterations. We are convinced that doses which appear to produce no effect on the blood pressure may cause definite effects in the mental status. In this respect in certain sensitive persons doses as low as 1 mg have produced such a response. Psychological stimulation from doses of $2\frac{1}{2}$ mg has been reported by others^{10-12, 24}. However, we have found a few patients unresponsive to doses as high as 70 mg. Subcutaneously 9 mg and intravenously 5 mg are effective in elevating the blood pressure. No smaller doses have been reported to date.

(b) *Toxic Effects*—It is difficult to draw the line between beneficial and harmful effects of the drug because a reaction such as disturbance of the sleep mechanism might be favorable at one time (as in narcolepsy) and unfavorable at another (as in insomnia occurring in orthostatic hypotension). Many authors have mentioned such situations in which excessive psychic stimulation was corrected by reduction in dosage. We have summarized the untoward effects in a previous publication.¹ Toxic effects may be considered to be an aggravation of the usual reaction to the drug from excessive dosage, the occurrence of alarming and harmful reactions from small dosage (idiosyncrasy), and the occurrence of unpredictable or paradoxical responses which, because of their severity, are dangerous to the patient. We have observed at times that overdosage has produced assaultiveness, confusion, hallucinations, and delirium, that dementia praecox patients have been precipitated into panic, that mentally ill persons have made suicidal or homicidal attempts, that a few patients have shown cardiac and vasomotor collapse associated with paradoxical falls in blood pressure and pulse. Similar observation has been reported by Anderson and Scott.²⁰ Pre-cordial pain and disturbances of rhythm and conduction were recorded by them. Aggravation of psychoses was also noted by other observers.^{22, 26}

The toxic effects of continuous inhalation of benzedrine were reported by

Waud²⁵ to include sympathomimetic excitation, stimulation of the central nervous system which is marked but relatively temporary and always followed by fatigue and mental depression, marked but temporary pressor effect, diuresis, and depression of the cardiac muscle. He concluded that permanent organic changes are probably negligible with normal doses of benzedrine over long periods of time, and that the margin of safety is great in normal persons.

Eight cases of severe reactions have been reported.

1. Davies patient²² developed aplastic anemia with cardiovascular collapse from 100 mg during nineteen days.

2. Extreme panic in a student three hours after 30 mg was reported by Ulrich.⁴⁹

3. Meerloo's student¹⁹ became violent after taking 90 mg daily for three weeks.

4. Donley's patient¹⁸ developed hypertension and jaundice after receiving 20 mg daily for two weeks and expired one week later from pneumonia.

5, 6. Two of Finkelman and Shapiro's patients⁷ died from pneumonia during an influenza epidemic while receiving 10 to 20 mg of the drug for postencephalitic Parkinson's syndrome.

7. Unconsciousness and clonic convulsions nine hours after 30 mg were reported by Smith and Chamberlin.⁴⁰

8. The ingestion of a single dose of 140 mg with suicidal intent by Appelberg's patient²⁷ resulted in coma of thirty six hours duration, convulsions, circulatory collapse, signs of cerebral irritation and depression, and eventual recovery. This person also developed pneumonia and four subcutaneous abscesses. The occurrence of infection of the upper respiratory tract and the skin is worthy of comment.

Although many untoward, paradoxical, and unpredictable effects of benzedrine sulfate occur, the exceedingly alarming reactions just mentioned must be considered to represent idiosyncrasy to the drug or the result of gross overdosage because of the large number of patients in whom no such serious effects have appeared.

(c) *Habituation*—A number of our patients have enjoyed the sensations produced by benzedrine sulfate, and have requested further doses of the drug. This was particularly true of those who had a liking for spirituous liquors. Some individuals compared their sensations with those of a mild state of alcoholic intoxication. We are convinced that in certain persons at least, benzedrine sulfate is habit-forming. We have noticed this tendency in individuals addicted to alcohol, morphine and other drugs, in neurotic persons who crave medication, and in people who work under excessive strain such as actors, students, nurses, and physicians. The benzedrine habit appears to be similar to the daily use of moderate amounts of caffeine, nicotine, and alcohol. At present there is insufficient evidence to definitely establish whether the patient is worse after benzedrine has been discontinued than he was prior to its administration. The development of tolerance, which has been mentioned,^{11, 12} is consistent with habit formation.

Byrne⁵³ in 1933 commented on the similarity to cocaineism of the effects produced by excessive benzedrine inhalation. Peoples and Guttman⁵ early called attention to the danger of addiction, and Guttman and Sargent¹⁴ later mentioned individuals who were buying the drug at pharmacies without medical supervision. They felt that the preponderance of disquieting somatic symptoms and the insomnia would tend to make addiction rare. Hill²¹ made similar comments. Ulrich,⁴⁹ Meerloo,¹⁹ and Davies⁸³ have reported cases of students who have taken the drug for aid during examinations. In a series of 147 students, Gwynn and Yater²³ found that thirty-eight had a definite desire to continue taking the drug. Reports of promiscuous use of the drug by students in at least two of our large universities have appeared in the lay press⁹⁴⁻⁹⁶. Numerous editorials⁹⁷⁻¹⁰⁴ in the American and British medical journals have warned against such practices. Reiter²⁰ has pointed out that in Germany the drug has been widely

advertised in newspapers as producing "the same effect as a two month vacation." Waud²⁵ has informed us¹⁰⁵ that the person in whom he studied the effect of continuous inhalation was very reluctant to give up taking the drug, in spite of the marked toxic manifestations that had been produced. This person developed a definite tolerance to the drug. Myerson, however, has stated¹⁰⁶ that the drug does not cause addiction, because "it does not leave the patient at a lower level when the effects wear off."

XV. Summary of Pharmacologic Physiology of Benzedrine Sulfate

An analysis of the foregoing review of the pharmacologic physiology of benzedrine sulfate reveals considerable controversial and unconfirmed data. The pattern of reaction is variable, uncertain, unpredictable, and, at times, paradoxical depending upon the individual medicated and the opinion of the investigator.

The need for further investigation is apparent. The effect of the drug on the genitourinary tract and the renal function, the mode of excretion of the drug, and the concentration of the drug in various body fluids are among the many problems that suggest themselves.

THERAPEUTIC APPLICATION

A review of clinical experiences with the drug in the treatment of various diseases and conditions will now be presented.

I Nervous and Mental Disease

(a) *Narcolepsy*—In 1935 Prinzmetal and Bloomberg⁴ reported the first use of benzedrine sulfate in narcolepsy. They found oral doses of 10 to 90 mg daily satisfactory in nine patients and concluded that benzedrine was three times as effective as ephedrine. Bloomberg¹⁰⁷ in a later report states that thirty-five cases of narcolepsy treated by him have received complete relief from attacks of sleep and cataplexy. Since these reports numerous investigators^{6, 7, 9, 10, 14, 15, 17, 37, 49,} have recorded a total of fifty-eight

patients with narcolepsy who have been treated with benzedrine sulfate. Of these ninety-eight per cent obtained relief from the attacks of narcolepsy. Davidoff⁷ reported a narcoleptic patient with a psychotic state who showed improvement of the narcolepsy but an aggravation of the delusions and hallucinations. A similar experience was mentioned by Solomon, Mitchell, and Prinzmetal.¹⁶ We observed that benzedrine sulfate had no effect on the narcoleptic attacks of a patient who subsequently was proved at postmortem to have Wilson's disease.

(b) *Postencephalitic Parkinsonism*—In March 1936, Solomon and Prinzmetal¹⁰⁸ reported a series of eighteen cases of postencephalitic Parkinsonism who showed beneficial responses to benzedrine sulfate. Bloomberg¹⁰⁹ and Davidoff⁷ shortly after mentioned that such patients showed a favorable response to benzedrine sulfate and stramonium or scopolamine. Later Solomon, Mitchell, and Prinzmetal¹⁵ presented a series of twenty-eight cases and reported that fifty-three per cent were benefited by benzedrine alone, while ninety-three per cent were improved on a combination of benzedrine sulfate and stramonium or scopolamine. The dosage required was 10 to 160 mg daily. The improvement was observed chiefly in the subjective symptoms and to a lesser extent in the tremor and rigidity. These authors found benzedrine sulfate of no value in cases of arteriosclerotic Parkinsonism. To date one hundred fifty-nine cases of postencephalitic Parkinsonism have been reported^{77-79, 109} as treated with benzedrine sulfate combined with scopolamine, stramonium, or atropine. Of these, eighty-five per cent showed improvement. Beneficial response has been recorded in ninety-five per cent of twenty-one cases with oculogyric crises.

In our experience benzedrine sulfate has been a beneficial adjuvant to stramonium, scopolamine, or atropine in four of six patients with postencephalitic Parkinsonian syndrome when there were minimal organic defects and personality

changes. However, patients with demonstrable psychotic states were not as favorably influenced.

(c) *Myasthenia Gravis*—Fraser, McGeorge, and Murphy¹¹⁰ briefly mentioned some beneficial effect from benzedrine given in combination with prostigmin in one case of myasthenia gravis. Thorner and Yaskin¹¹¹ treated five cases of this disease. Three patients showed a more satisfactory response to a combination of benzedrine sulfate and prostigmin than to either drug alone.

(d) *Alcoholism*—In states of alcoholic intoxication without psychosis we have found that benzedrine sulfate usually produced a very satisfactory response. The headache, fatigue, languor, and mental retardation characteristic of a "hangover" were rapidly dissipated by 10 mg. A similar response has been mentioned by Wilbur et al.^{11, 12} We have been able to arouse within thirty minutes several patients with alcoholic stupor by injection of 10 to 30 mg of the drug intravenously.

(e) *Barbiturates and Morphine*—We have found²² that benzedrine sulfate will quickly arouse patients intoxicated with mild doses of barbiturates. However, in poisoning from massive doses results have not been as favorable because of the physiologic depression by the barbiturate of the respiratory center which is unresponsive to benzedrine, and because of the extent of the toxic pathologic process. There is some evidence to indicate a synergy of harmful effect in combined massive doses of both drugs. In stupors due to morphine, benzedrine sulfate appears to be of value in shortening the comatose period when used in conjunction with the other recognized procedures. The drug appears to be of value in counteracting withdrawal symptoms.

(f) *Organic Psychoses*—In our experience,²² in the organic psychoses characterized by depression the states of intoxication were more favorably influenced than those of infectious or traumatic origin. In alcoholic psychoses of

recent onset ninety-three per cent of twenty-eight cases were benefited.⁸⁶ Fifty per cent improvement was observed in psychoses of recent onset due to encephalitis. Sixty-seven per cent of the early traumatic cases showed improvement. In organic psychoses where defects of the sensorium, deterioration, or personality alteration had developed, the response was unsatisfactory. In psychoses resulting from intoxication with barbiturates and morphine we have noted results comparable to those of the alcoholic group.

(g) *Dementia Praecox*—For over two years we³⁴ have been using benzedrine sulfate orally in the treatment of self-absorbed dementia praecox patients. Thirty-three per cent of forty-five cases showed improvement as compared with twenty-four per cent in a control group of 300 cases. However, of nineteen recent cases forty-seven per cent improved in contrast to fifteen per cent of twenty-six cases ill longer than two years. Recently we have been employing in all types of dementia praecox a procedure which combines on alternate days narcosis with sodium amytal orally and stimulation with 30 mg of benzedrine sulfate intravenously. To date sixteen cases have been treated and of these eight have been discharged to their homes.

Myerson,²⁴ Carlisle and Hecker,⁹⁰ and Schube et al.⁸⁰ have reported no improvement in patients with dementia praecox, while Guttman and Sargent,¹⁴ Donley,¹⁸ and Bloomberg¹⁰⁷ have reported transitory improvement in a limited number of cases. Woolley²² found improvement in eleven out of forty-four cases.

We have concluded that in those cases of schizophrenia which are inherently capable of being stimulated to some degree of improvement, benzedrine sulfate may initiate, accelerate, augment, and/or indicate such improvement. Long continued observations of a large series of patients correlated with adequate control studies will be necessary before we can determine the value of the benzedrine

sulfate procedures in the treatment of dementia praecox. Until recoveries from this mental illness are recorded as "five and ten year cures," as is done in estimating response in neoplastic disease, we will be unable to evaluate properly the worth of any of the pharmacotherapeutic procedures now in vogue.

(h) *Manic Depressive Psychosis, Depressed Type*—Guttman and Sargent¹⁴ reported encouraging results in mild depression but noted little effect in severe depression or stupor. Myerson²⁴ stated that in mild psychoses associated with depression, fatigue, and anhedonia, benzedrine sulfate acted as an ameliorative influence. In a later communication Schube et al.⁸⁰ reported that the drug had no value in the alleviation of a series of thirty-two patients with depression of the manic-depressive type.

We have found the rate of improvement apparently accelerated in thirty per cent of twenty patients with this psychosis. In half of the cases a state of increased irritation was produced, while in only six was there an elevation of mood. Because of the inherent tendency of this group to improve, it was difficult to evaluate the effect of the drug. Wilbur et al.^{11, 12} found that seventy per cent of patients with depression were benefited immediately by the drug, but over periods of one to eight months only twenty-five per cent continued to show improvement. Donley¹⁸ reported transitory improvement in two cases, Reiter²⁰ found marked improvement in five of twenty-six cases, and Woolley²² observed a favorable response in four of seventeen.

We do not consider that any of the investigators to date have sufficiently studied the possibilities of benzedrine sulfate in this psychosis. Adequate control data are also needed. We feel that theoretically the drug is not suitable for use in severe states of depression because of our previous observations that the drug has less effect in elevating mood than in producing acceleration of motor and speech activity.

(i) *Psychoneuroses*—Myerson²⁴ re-

ported that benzedrine sulfate has an ameliorative influence on the morning apathy occurring in certain cases of psychoneurosis associated with depression, fatigue, and anhedonia. Nathanson¹ found that the drug acted favorably in eighty per cent of states of "persistent exhaustion" and in individuals who became easily fatigued. Wilbur et al.^{11,12} also stated that eighty per cent of patients with chronic nervous exhaustion received immediate benefit which was maintained over a period of one to eight months in only fifty per cent. These observations of Nathanson and Wilbur have been included by us under the heading of psychoneuroses because we believe that when underlying organic disease or excessive physical strain cannot be uncovered as the cause of the persistent fatigability, a psychoneurosis exists. We have previously advised caution in administering the drug in states of asthenia associated with malnutrition, exhaustion, anemia, debility, and lowered bodily resistance. If these authors are including in this group of patients those exhibiting the ill-defined concept of vasomotor instability, we will agree that people with a labile vasomotor system are more sensitive to the drug as we have pointed out along with Peoples and Guttman,⁸ Shapiro,¹⁰ and Hill.²¹

We encountered the greatest difficulty in evaluating the effect of benzedrine sulfate in the psychoneurotic group. Most striking was the lack of consistent improvement in all phases of response in any given case. Amelioration of the predominant psychoneurotic complaint was found in only twenty seven per cent of fifteen cases. Elevation of mood occurred in the same percentage. Solomon et al.¹⁴ found improvement in only two of twenty-two patients with psychoneurosis. Wilbur et al.^{11,12} in a group of thirty five patients whom they diagnosed as psychoneurotics observed improvement in forty seven per cent. Reiter²⁰ reported improvement in ten of sixteen cases, with marked improvement in only three. Woolley²² noted favorable response in one of five patients

We have observed, as have Guttman and Sargent¹⁴ and Shapiro,¹⁰ that anxiety states are usually aggravated by the drug. For this reason we hesitate to administer the drug to persons with anxiety neuroses, involution melancholia, and mixed manic psychoses.

II Cardiovascular Disease

In one case of orthostatic hypotension Korns and Randall²¹ found that divided doses of benzedrine sulfate totaling 100 to 150 mg daily were adequate to give relief of symptoms over a period of six months. Davis and Shumway Davis^{11,12} noted similar results in two cases with divided doses totaling 55 to 75 mg daily. Wilbur et al.^{11,12} reported a satisfactory response in one case, and we have seen one mild case that was favorably influenced.

Tovell¹² found the drug of some value in combating shock and hypotension during operations under spinal anesthesia. In a series of patients²² in whom sodium amytal narcosis was experimentally induced, we found that benzedrine sulfate intravenously consistently elevated the blood pressure. One patient in collapse with a blood pressure of 50/0 experienced an immediate rise to 140/90.

Benzedrine sulfate therefore appears to be of some value and worthy of further clinical trial in orthostatic hypotension and in hypotension due to shock. In other syndromes associated with hypotension, the underlying causative pathology must be carefully determined before it can be decided whether the drug should be tried for its pressor effect. It must be remembered that paradoxical depressor responses have frequently occurred, even though the drug usually produces elevation, particularly when the initial blood pressure is low.

III Gastrointestinal Disease

Although considerable controversy exists over the action of benzedrine sulfate on the gastrointestinal tract, as has been mentioned, most investigators agree that the drug is of value in selected cases in relaxing the spasm of hypertonic states of the stomach, the duodenum, the small

intestine, and the colon to aid in roentgenographic study of these organs. To date there is insufficient data to warrant the use of the drug in the treatment of pylorus spasm and spastic colitis. It must be pointed out that as yet the drug cannot be advocated for routine use in roentgenographic study of the gastrointestinal tract because of the occurrence at times of increased peristalsis, peristaltic rushes, to-and-fro churning, and occasionally sufficient relaxation to produce stasis with flatulence and uncomfortable distension. The increase in gastric acidity reported by one observer would make the use of the drug undesirable in patients who are already afflicted with hyperacidity, as in gastric ulcer.

IV Upper Respiratory Tract Diseases

The value of benzedrine vapor by inhalation from the "Benzedrine Inhaler" in diseases of the upper respiratory tract is too well known to need comment here. Internally the effect of benzedrine sulfate on this system is too uncertain to merit therapeutic application.

V Ophthalmological Applications

The beneficial effects of benzedrine sulfate internally on the oculo-gyric crises of postencephalitic Parkinsonism have been previously mentioned. The instillation of benzedrine solution in the eye in combination with homatropine or atropine to produce a rapid cycloplegia of short duration is a procedure which appears to have considerable merit.

VI. Weight Reduction

The use of benzedrine sulfate for the reduction of weight has been advocated by Myerson and his associates.⁸² However, in their study the drug was used in combination with a marked restriction of diet in obese psychoneurotic patients. On the basis of the existing data of other observers, we feel that there is doubtful value in the use of benzedrine sulfate as a routine medication to induce weight reduction in office or clinic practice, particularly in view of the rela-

tively mild initial loss of weight which occurs and which is frequently not maintained, and further that there is possible harm in view of the untoward effects which may ensue. In institutions where a definite routine and proper precautions can be employed, the drug may be used during a short period of administration to initiate a loss of weight maintained by the establishment in the mind of the patient of a psychologic state which enables him to adhere to the regime.

VII Miscellaneous Therapeutic Applications

Hill²¹ used benzedrine sulfate in treating one hundred cases of seasickness with satisfactory results in thirty-nine, and doubtful improvement in an additional forty. He stated that the drug has great possibilities of usefulness in certain cases of seasickness in which there are signs of excessive vagus activity. Robinson^{87,88} in four cases found that doses of 20 to 30 mg of benzedrine sulfate at four hour intervals were usually effective in preventing induced and spontaneous syncope resulting from a hyperactive carotid sinus reflex (Stokes-Adams attacks). Poole and Wilkinson¹¹⁴ reported the disappearance of heart block in one case following small doses of the drug. On the basis of the report of Molitch and Poliakoff⁸⁹ there may be a restricted use for the drug in overcoming nocturnal enuresis when associated with deep slumber. Heisch¹¹⁶ suggested that benzedrine sulfate internally in combination with belladonna may have a beneficial effect in hay fever. Nathanson⁹ reported a favorable response from the drug in four cases of migraine.

We are at present studying the effect of benzedrine sulfate in asthma and in the vomiting of pregnancy. Theoretically the drug may have usefulness in all cases where ephedrine has previously appeared to be of value.

Contraindications

The following are definite contraindications to the administration of benzedrine sulfate.

- 1 Hypertension
- 2 Coronary artery disease.
- 3 A state of excitement.

In addition, there are a number of circumstances in which benzedrine sulfate should be administered with considerable caution, because of possible harmful effects. We include among these the following

- 1 Indiscriminate use of the drug for symptomatic relief without adequate supervision or thorough investigation
- 2 Outpatient practice
- 3 Idiosyncrasy to small doses of the drug, or the early appearance of alarming untoward effects
- 4 More severe forms of vasomotor instability
- 5 Wide daily fluctuations in the blood pressure or pulse rate
- 6 Generalized arteriosclerosis
- 7 Senility
8. Atonic states of the gastrointestinal system
- 9 Hepatic insufficiency and thyroid hyperfunction
- 10 Tendency to physical overactivity
- 11 Agitated depression
- 12 History of previous excitement, as in mental deficiency and epilepsy
- 13 History of homicidal or suicidal tendencies
14. History of convulsive seizures
- 15 Anorexia
- 16 Insomnia.
- 17 States of asthenia associated with exhaustion, debility, anemia, and lowered bodily resistance.
- 18 Psychopathic personalities and other individuals where habituation is apt to occur
- 19 Persons who request the drug

The increased sensitivity of individuals with asthenic habitus should be considered, particularly in unsupervised regimens. It has been our opinion that this drug should not be used in cardiac and vascular disease until more is known of its action. For reasons now apparent, we must condemn the use of benzedrine sulfate in preparing individuals for periods

of excessive physical or mental exertion. In severe depressions the possibility of suicide must always be borne in mind. Habituation, which definitely occurs in some individuals, demands constant vigilance.

Indications

Benzedrine sulfate as an internal medication is best established in the treatment of narcolepsy. On the basis of the insufficiently confirmed reports in the literature to date, the drug also appears to have some therapeutic usefulness, subject to the limitations previously pointed out, in the following conditions: (1) postencephalitic Parkinsonism, but only as an adjuvant to stramonium, scopolamine, or atropine and (2) states of hypotension, as orthostatic hypotension, and hypotension due to shock.

Additional therapeutic suggestions in need of much confirmatory data include

- 1 Spasm of the gastro-intestinal tract, but only as an aid to roentgenographic visualization
- 2 States of depression of recent onset due to drugs, particularly alcohol and moderate doses of barbiturates
- 3 States of depression of recent onset due to infection or trauma
- 4 Self absorbed states of dementia praecox of recent onset where it may, initiate, accelerate, augment, and/or indicate improvement which is inherently present, and where it may act as an adjuvant to other psychotherapeutic procedures
- 5 Manic-depressive psychoses of the depressive type.
- 6 Psychoneuroses
- 7 States of vagus overactivity, as seasickness or hyperactive carotid sinus reflex (Stokes-Adams syndrome)
- 8 Weight reduction, but only as an initial procedure in an institutional regime.
- 9 Myasthenia gravis

Benzedrine sulfate can be more safely prescribed when the patient is under observation in a hospital, but may be satisfactorily administered in outpatient prac-

tice when given with great caution under the most favorable circumstances and careful supervision

Benzedrine by inhalation or local application is well-established as an astringent of the upper respiratory tract. Its use as a solution to produce cycloplegia seems to have considerable merit

Summary

- 1 The present status of benzedrine sulfate therapy based on a review of the literature and on the experience of the authors is herein presented
- 2 The pharmacologic physiology of the drug is discussed
- 3 The various therapeutic applications that have been made of the drug are described
- 4 Emphasis is placed on the unconfirmed and controversial nature of much of the reported data, on the occurrence of untoward effects and habituation, on the danger of indiscriminate use, and on the necessity of administering the drug with caution
- 5 The present indications and contraindications of benzedrine sulfate are outlined

A FEW TIMELY DON'TS

The committee on fractures of the American College of Surgeons has announced a series of rules for laymen and physicians to follow in first aid to victims of injuries to the spine. Among the rules are

Unless there is imperative need to move an individual suspected of having a spinal injury to a zone of safety the injured is best not moved or lifted until medical aid reaches him. If the injured must be moved the committee proposes the following first-aid methods

If a patient complains of pain in his back he may have a broken back. If he complains of pain in his neck he may have broken his neck. Never lift an injured person or his head until he has told you whether he can move his legs or fingers. If he cannot move his legs his back is broken. If he cannot move his fingers, his neck is broken. In both cases the spinal cord is injured. If you lift his head to give him a drink of water or if you fold him up to carry him, you inevitably grind the injured spinal cord between parts of the broken spine and destroy any useful remnant of the spinal cord which may have escaped injury in the accident. Do not allow the victim to sit up

SUPERSTITIONS NEVER DIE

Some of the money being raised for the voluntary hospitals by the United Hospital Campaign Committee will be used to rid patients of their superstitions

Every day in the hospital clinics some age-old superstition turns up. And it isn't only the illiterate who believe in them.

Here are a few revealed in a survey by the campaign committee

A junior at Columbia University came to one of the clinics for an earache. In the ear the doctor found a small piece of garlic which the student had placed there in the hope it would drive away the ache. It was a variation of the old device of hanging a bag of garlic around the neck.

Then there is the professor of metallurgy who from October 1 to May 1 always wears a girdle of two thicknesses of red flannel ten inches wide around his waist to ward off colds. The professor told the Medical Center doctor that the band works.

Another doctor at one of New York's largest voluntary hospitals said a patient from one of the wealthiest sections of the city came to him for treatment for dog bite.

Under the bandages the doctor found a long black hair—the hair of the dog that hit the man

On leaving school every Scottish boy and girl will be presented with a copy of 'The Rules of Health' an attractively printed booklet issued by the Department of Health. There are six short paragraphs under the headings 'Fresh Air and Exercise,' 'Rest,' 'Food,' 'Care of the Body,' 'Medicines' and 'Care of the Mind'

Assemblyman Irwin Steingut, of Brooklyn, has announced that he will introduce a bill at this session of the legislature to set up a system of state health insurance, according to the New York papers.

THE TRYPTOPHAN REACTION

An Aid to the Early Diagnosis of Meningeal Tuberculosis

J ARTHUR BUCHANAN, M D , and HARRY BALLWEG, M D , Brooklyn

THE diagnosis of meningeal tuberculosis in adults offers a difficult problem in many instances. The tryptophan reaction as modified by Baxter of Glasgow offers assistance.¹ We report the following case which was positively diagnosed prior to death by the use of the Baxter modification. The test is used in other countries, but rarely in the United States.²⁻⁹

Case Report

On November 6, 1937, a twenty-seven-year-old white, married, somewhat obese female entered Wyckoff Heights hospital with stiffness and aching pain in the neck. For about two weeks previously there had been general malaise, headache, and weakness. During the week previous to admission there had been frequent vomiting of a regurgitant nature, and moderate diarrhea, both of which ceased before admission. For two days before admission, the patient had experienced generalized abdominal cramps. The nuchal rigidity and pain developed on the day of admission. Past medical and family history were entirely negative.

The patient appeared listless, but oriented and mentally clear. Rectal temperature was 100.4° F, pulse ninety-two, respirations twenty-four. There was marked nuchal rigidity, positive Kernig's sign bilaterally, and right Babinski. Abdominal reflexes were absent, likewise the knee jerks and other tendon reflexes. There was generalized skin hyperesthesia. The fundi showed all details of eye grounds hazy and somewhat obliterated. The discs were not swollen, but the margins were somewhat indistinct. The retinal vessels, especially the veins, were overfilled and tortuous.

The urine analysis was negative. The hemogram showed a moderate polymor-

phonuclear leukocytosis. The spinal fluid showed a pressure of forty mm of mercury. The fluid was clear and contained 450 white blood cells per cu mm, of which ninety-five per cent were lymphocytes. The globulin was increased and sugar absent. No organisms were seen on Gram stain, Ziehl-Neelsen stain, or in culture. The blood and spinal fluid Wassermann reactions were negative. A nontypical fibrin web developed in the spinal fluid on standing.

Tuberculous meningitis was suspected, although there was nothing in the history or the nutrition of the patient to substantiate the diagnosis. The organisms could not be demonstrated microscopically in the spinal fluid. A guinea pig was inoculated with the fluid. While waiting for the results of the inoculation the tryptophan reaction as modified by Baxter was carried out and yielded a positive result on November 10.

The patient became more drowsy, stuporous, developed ocular palsies, became comatose, and died November 17. Spinal puncture had been performed daily and a steady increase in the fluid pressure was noted. Except for minor changes in the spinal fluid cell count from day to day, the findings were stationary. The tryptophan reaction was positive the second time on November 14, but the reaction was not studied on the intervening days. The test when carried out as described by Aiello gave negative results.¹⁰

At autopsy, a glary mucoid fibrinous exudate was found attached to the dura mater at the base of the brain. Similar plaques were found on the superior surface of the cerebrum. The bacillus of tuberculosis was demonstrated in this exudate. At the hilus of the left lung a small lymph node, one cm in diameter

was found. It was undergoing caseous necrosis and evidently was the disseminated focus.

Technic of Test

Reagents needed (1) Hydrochloric acid (concentrated) (2) Two per cent formalin solution. This is made by diluting formaldehyde 1:20 with distilled water. (3) 0.06% sodium nitrite solution.

Steps Place two or three cc. of spinal fluid in a large test tube. Add fifteen to eighteen cc. of hydrochloric acid and two or three drops of two per cent formalin. Shake well and let stand for four minutes. Carefully layer with one or two cc. of sodium nitrite solution, and let stand for two minutes.

Reaction The test is considered positive when a delicate violet ring is apparent at the juncture of the mixture and the sodium nitrite solution. Brown rings are to be considered as negative.

Blood stained or frankly purulent fluids are not to give pseudo-positive reactions.

NOTE In the test as described by Aiello¹⁰ 0.5 to 0.8 cc. of concentrated hydrochloric acid were used.

Summary

The tryptophan test as modified by Baxter should be used as a diagnostic aid in the study of otherwise undiagnosable cases of meningitis. This case is reported to stimulate interest in its use, as it is not in common use at the present time.

SURGICAL TREATMENT OF DISEASES OF THE COLON

THOMAS E JONES, M D , Cleveland, Ohio

IN THIS communication, only the more common conditions of the colon which require surgical treatment will be considered, namely, diverticulitis, polyposis, chronic ulcerative colitis, regional ileitis, and cancer of the colon

Diverticulitis

The surgical problems which are present in the treatment of diverticulitis do not, I believe, parallel those in acute appendicitis. In reading case reports in the literature, one is impressed by the number in which exploratory operation was done in the acute phase of the disease with termination in death due to peritonitis within a few days. One is justified in wondering whether or not a certain percentage of these cases might have localized in a period of days and surgical intervention later might have been safer. Personally, I think that this condition calls for more individualization than does acute appendicitis and, while one may make generalized rules, each case must be studied carefully.

One clinical fact is outstanding—even though the diverticula may be very extensive and invade the entire colon, diverticulitis with its complications is practically always confined to the sigmoid colon. This is probably due to the smaller caliber of the bowel and the firmer stool in the sigmoid area.

The symptoms of diverticulitis vary greatly according to the pathologic condition found. There may be only mild attacks of pain in the left lower quadrant or there may be any graduation up to the signs and symptoms arising from the graver complications, namely, perforation with peritonitis, obstruction, or localized abscess with eventual formation of a fistula. An accurate history is invaluable in establishing a correct diagnosis. Differential diagnosis will not be discussed here.

Any given case in which operation is

not performed will terminate in one of the following ways

1 It may completely resolve, but this does not militate against subsequent attacks either in the same diverticulum or in others in the same segment. This is the chronic variety and strict medical management should be instituted to prevent recurrence.

2 Perforation may occur

(a) Into the rectum with discharge of pus. This is a fortunate and happy sequel.

(b) Into the bladder. This is an unfortunate complication.

(c) Into the surrounding tissues where it generally is walled-off.

(d) Without becoming walled-off but is generalized with resultant peritonitis. This is the exceptional case and not the rule.

3 Obstruction may result where the process is not resolved. This is due to the great thickening of the mesentery and all coats of the bowel.

The problem that confronts us then is, should we operate, and, if so, when is the optimum time? The fulminating cases are so rare that the diagnosis is seldom made until a well-advanced peritonitis has developed for which surgery is of no value. Most of the cases are of the subacute variety and, as the problem does not constitute an emergency, sufficient time may be taken to make a more accurate diagnosis. Roentgen examination is of great assistance in localizing the diverticula and their extent, so with this knowledge, a well-planned operative procedure may be carried out.

In cases where the symptoms of obstruction are predominant and there is little or no rise in temperature and a mass is detected either by bimanual or abdominal palpation, operation must be performed for the relief of the obstruction. If roentgen examination has shown

the diverticula to be limited to one segment of the bowel and if no abscess is present, then that segment may be removed by an operation of the Mikulicz type. This will insure the patient against future attacks. If, however, roentgen examination shows extensive diverticula in the sigmoid, the patient still may experience attacks in the remaining diverticula so that, in this type of case, I believe a colostomy should be performed well above the involved area. This will remove the symptoms of obstruction and allow the inflammatory process in the affected area to subside. The patient should keep the colostomy for at least six months and preferably one year, in the meantime, through and through irrigation of the distal segment should be carried out. After subsidence of all symptoms, the colostomy may be closed but the patient must be informed that a recurrence is always possible unless he follows a strict medical management of his bowel.

If a surgeon inadvertently discovers this condition during an exploratory operation for an acute abdomen, extensive surgery is contraindicated. A colostomy should be done well above the inflamed area and resection with anastomosis may be performed at a later date after the inflammatory process subsides.

In dealing with the subacute variety where the outstanding features are pain and temperature up to 100 or 101°, I am a firm believer in conservative management. If perforation into the rectum occurs, the problem is solved. If an abscess forms, it is generally lateral to the sigmoid and may be opened when the tumefaction appears, very much as an appendiceal abscess is evacuated. If symptoms of obstruction intervene during this period of waiting, a cecostomy or transverse colostomy should be done.

Following evacuation of the abscess, a fistula may result which may or may not close spontaneously. After a time, the fistula will be only a small sinus tract and I have seen closure occur as late as nine months after operation. Such a fistula causes little inconvenience to the patient and he should be encouraged to keep it be-

cause its closure is not a simple matter. Excision of the sinus with inversion of the bowel is very difficult to do and the fistula will recur in most cases, so that to obtain a cure it becomes necessary to do a resection of that segment of the bowel containing the fistula. That involves a three-stage procedure which is not often justifiable.

Particularly distressing are those diverticula which have become fastened to the bladder and which result in a vesicocolle fistula. Obviously something must be done surgically, but I feel very strongly that the surgeon should not go in, resect the fistula, close the bladder, and close the bowel in one stage. The mortality from peritonitis or reformation of the fistula under such circumstances will be high. It is eminently more satisfactory to do a preliminary colostomy and free the urinary tract from infection which has resulted from the fistula before the secondary operation is undertaken for repair of the fistula by whatever means may be indicated.

In a review of the last twelve cases which have come under my observation, I find that treatment varied to some degree so that I cannot present any definite plan which may be followed. The underlying principle of conservatism, however, could be traced throughout the series.

Polyposis

Polyposis of the colon may be either of two types—the congenital or familial type or the acquired or inflammatory type. The inflammatory type is the most common and is generally associated with ulcerative colitis. My discussion of this subject will be confined to the congenital or familial type.

Congenital or familial polyposis is a relatively rare condition but very important from the standpoint of incapacity of the individual and also because, if untreated and if the patient lives to adult life, 100 per cent of the polypi invariably become malignant. Adenomatosis is a more descriptive term than polyposis for this condition. These adenomata are found chiefly in the rectum and sigmoid

but may invade the entire mucosa from the rectum to the ileocecal valve and sometimes beyond that. It is definitely familial in type and has been traced through three generations in many families and anywhere from forty to eighty per cent of the offspring will be afflicted. McKenney¹ of Buffalo has done a magnificent piece of work along these lines by tracing it through many families.

Ewing² states that nowhere else can the change from normal mucosa to gland cell hypertrophy, adenoma, and adenocarcinoma be so clearly demonstrated as it may in this disease. Malignant degeneration of these adenomata may be single or may occur simultaneously in many, as demonstrated in several of our cases.

From the standpoint of diagnosis, I should like to warn against a feeling of security when a biopsy report shows no malignancy. This is very misleading, for it may well be that a polyp higher up and out of sight is malignant.

The original treatment advised was ileostomy with complete colectomy, this being the only thing that would insure against malignant degeneration. This was a very formidable procedure and the mortality was high. Furthermore, ileostomy with its continuous liquid drainage is far more distressing than colostomy with solid stool. For these reasons, patients were frequently neglected. A report of the following case will serve to illustrate what I believe is a better procedure for the handling of this condition.

In 1926 I was consulted by a twenty-five-year-old woman who was suffering from multiple, congenital adenomatosis. The diagnosis was made elsewhere and surgical treatment advised. This was refused when the patient learned of the permanent ileostomy. When she consulted me months afterward, she was having considerable hemorrhage, diarrhea, and pain which indicated the presence of obstruction. She was very anemic and there was a marked loss in weight. After considerable urging, she finally consented to a cecostomy which I told her would probably be temporary and could be closed after the symptoms of obstruction

had disappeared. During the next few months she had gained considerable weight and the symptoms of toxemia disappeared following through and through irrigation of the colon. Bleeding still occurred, however. On proctoscopic examination I noted that the size of the adenomata had decreased considerably from that seen at the original examination. Much of the edema and inflammatory reaction had disappeared due to less infection. In order to stop the bleeding, I began to fulgurate these adenomas of which there were hundreds in the rectum and sigmoid. This was repeated monthly for many months, fifteen to twenty adenomas being destroyed at each time. The patient felt so well and happy that I confess that I did not concern myself with the future.

Suddenly it occurred to me that I had cleared the way high enough so that I could make an anastomosis between the ileum and the sigmoid and remove the remaining colon from the sigmoid to the cecum, thereby preserving the rectum where none of the adenomas had recurred. Why this did not occur to me before I do not know because it would have saved valuable time. However, when I approached her with what I thought was a splendid idea, she was feeling so well that she declined operation. Finally, however, after about six months' urging and also due to the fact that there was still some bleeding from the adenomas out of reach, she decided to submit to operation. I performed an ileosigmoidostomy below the point where I could feel the adenomas, and six weeks later removed the colon which contained hundreds of polyps from the cecum to the sigmoid, many being ulcerated. She made an uneventful recovery, gained sixty pounds in six months, and felt well for nearly four years. Then she came in complaining of a mass in the left lower abdomen. Proctoscopic examination revealed no adenomas in the rectum. Exploration revealed a hard mass of glands retroperitoneally which proved to be adenocarcinoma of the mucoid type. What had happened, of course, was that one of these many adeno-

mas had become malignant and there was glandular involvement, although not apparent at the time of the colectomy. Obviously it was impossible to make sections of all these adenomas from the specimens removed.

The moral of this case, of course, is to perform the colectomy earlier. Here we lost about three years of valuable time. In recent cases we have sent the patients to the hospital and, under spinal anesthesia, cleared up the condition in the rectum and sigmoid in one or two sittings, then performed the operation. I have just described as soon as possible. I believe that by this method of treatment where we can promise restoration of the continuity of the bowel, we will be able to secure these patients' co-operation earlier and the future should be much brighter.

Chronic Ulcerative Colitis

Chronic ulcerative colitis has been attacked perhaps by more different types of therapeutic agents than any other disease with the possible exception of pruritus ani. It has always been recognized as a desperate condition when it necessitated surgical intervention, for many of these patients were moribund when they arrived for surgery. The older surgical method was that of ileostomy to sidetrack the fecal stream and thereby put the colon at rest. By this procedure and the use of irrigations, a certain number of individuals could be salvaged. Surgery, due to the failure of medical means, was making progress and patients were treated earlier until Bargen ascribed the etiology to an organism of the diplostreptococcus variety. This again stimulated medical men to use sera and vaccines, and again the only patients the surgeon saw were those who could not come into the office for more injections. Again the mortality of ileostomy took a sudden rise, for many of these patients had perforations and peritonitis.

From what information I have, it seems that the new sera and vaccines have been disappointing in the hands of most medical men and, until the time when something more promising comes along, I be-

lieve we must go back to surgery in the earlier cases. I am sure no surgeon relishes these cases but we would rather have early ones than late. I think the medical man must be fair in the evaluation of his treatment and, if it fails, he must admit it early and refer his patients to the surgeon before months or years have elapsed. It must be borne in mind that many of these patients have spontaneous remissions from recurring attacks, which may be attributed to the therapy instituted, but yet on proctoscopic examination there may be little or no change in the gross appearance of the bowel wall. The remission from symptoms merely means that the acute flare up higher in the bowel has become chronic and with succeeding attacks more of the bowel wall becomes involved so that eventually the whole colon from the rectum to the cecum is affected. It is generally conceded that this disease begins in the rectum in at least ninety per cent of the cases and extends upward with each succeeding exacerbation. I think that we are again in the place where we must advocate early diversion of the fecal stream to put the bowel at rest and then carry on such medical measures as are indicated.

From the surgical point of view, early operation is the only alternative in cases where it is hoped that the ulcerative process will subside so that the ileostomy can be closed at a later date. In the long-standing, neglected cases, the ulcerative process has destroyed the mucosa and infiltrated the muscularis with so much fibrous tissue that the lumen becomes greatly constricted, so that when ileostomy is done at this stage, one can never hope for physiological and anatomical restoration of the bowel sufficient to close the ileostomy with safety.

In some cases, ileostomy is sufficient for complete relief of symptoms. However, in a certain number of cases, the patient does not thrive and gain, due to absorption from the infected, ulcerated colon left in place, and colectomy becomes necessary. In view of the fact that these patients are a bad risk due to their poor physical condition, colectomy should be a graded pro-

cedure The colon should be removed in either two or three stages, removing the right half around to the mid transverse colon first, then the remainder down to the sigmoid and, lastly, the rectum In about ten per cent of the cases, the disease may be segmented, that is, it may be limited to the ascending colon or the transverse or descending colon or the sigmoid and yet the proctoscopic examination will give entirely negative findings I think that in the segmental variety the treatment of choice is early ileostomy or colostomy with resection of the affected area after a period of rest and irrigation In this manner the continuity of the bowel may be preserved

Heretofore, in the treatment of ulcerative colitis, the theme has been medical treatment versus surgical treatment when, as a matter of fact, it proves to be a bigger job than both can handle together The internist, the surgeon, and the proctologist must collaborate from the onset of the disease if better end results are to be obtained

Regional Ileitis

This disease entity, which was originally described as affecting the terminal ileum only, has been definitely shown to involve the colon also To Crohn³ of New York belongs the credit for stimulating our interest in this condition In my experience, when the colon was involved, the ileum was involved also, and it may have been and probably was the original sight of the pathology The symptoms at the onset closely simulate those of appendicitis and, in seventy-five per cent of our cases, the appendix had been removed In fifty per cent of our cases, the patient came in because of fistula after the appendectomy Formation of a fistula, either external or between the coils of intestine, is a characteristic of this disease

If a diagnosis of acute appendicitis has been made and the findings at operation are not in keeping with that diagnosis, it is a good principle to examine the lower few feet of the ileum If this acute inflammatory condition is found, I would advise against appendectomy because it

will frequently result in a fistula Surgery on the ileum is not advised during this acute phase—rather nothing should be done and the ileum removed after the inflammation has subsided and reached the chronic state If, however, there is some obstruction, an ileocolostomy can be made, using a loop of ileum at least two feet away from the disease process

When the colon has been involved in the cases I have seen, it has always been adherent and densely adherent to the small intestine with resulting fistulae between the coils

The treatment is surgery which consists of wide removal of the pathologic process, great care being taken during the procedure not to contaminate healthy structures The general principles underlying intestinal surgery apply here and, inasmuch as the surgical removal of certain segments will be referred to when malignancies of the colon are considered, I shall not discuss them here on account of their similarity

Cancer of the Colon

In recent years, many factors have contributed to encourage surgeons to attack the problem of cancer of the colon—improvements in technic, better pre- and postoperative care in hospitals, better selection of cases, all of which have increased the horizon of operability and lowered the mortality rate But there is small question that the greatest advance in surgery of the colon has come from the hands of the roentgenologist because the increased diagnostic efficiency has made for earlier recognition of organic lesions in this portion of the gastrointestinal tract. It is regrettable, however, that this efficiency has made too many of us lazy It has become too easy or perhaps too cheap to say "have an x-ray" without doing the simple digital and proctoscopic examinations which will establish the diagnosis in seventy-five per cent of the malignant lesions of the colon and rectum This is even more regrettable because a negative x-ray report on this particular location—the rectum and rectosigmoid—is absolutely unreliable on account of the

size of the rectal ampulla and the many coils which may obscure an accurate view. For his own protection, I would be happy to see the time come when a roentgenologist would refuse to do an examination of the colon unless the patient had had digital and proctoscopic examinations. A roentgenologist sit-down strike here would be invaluable to us all and would render a real service to the patient.

Cecum and Ascending Colon—A one or two-stage operation may be used for cancer of the cecum and ascending colon. In the two-stage procedure, the first stage consists in a side to-side anastomosis of the ileum to the transverse colon. It is obvious that an end to-side anastomosis cannot be made because, if something happens which delays the second stage for some time, the closed distal end of the ileum may blow out if obstruction intervenes. The second stage consists of the removal, being sure not to leave too large a blind pouch in the colon. I have always done the one stage in all cases except the occasional one where the ileum is dilated. The ileum is cut off and an end-to-side anastomosis made into the transverse colon. The Rankin clamp is very useful for this procedure, for a closed operation may be performed by its use. In the one stage operation it is essential or at least advisable to insert a catheter in the ileum about eight inches from the anastomosis. This remains in place for five or six days and acts as a safety valve.

Resection of the *transverse colon* may be done in many ways

1 Resection with end to-end anastomosis. This, however, is not a safe procedure in one stage.

2 Mikulicz type of operation. This is not entirely satisfactory because of the liquid contents in the transverse colon. It seldom closes spontaneously and repair must be done before it is eventually closed. Furthermore, incisional hernia generally results, which must be repaired later.

The preferable operation is to put a large tube into the cecum and ten to fourteen days later do a resection by the closed method with end to-end anastomosis,

using either the Rankin clamp or the Karr basting stitch. If the tube is properly sewn into the cecum, the sinus will close itself.

Fortunately, carcinoma of the *splenic flexure* is rare. I think it is probably the most difficult of all the segments to remove, because of the hip fixation. A Mikulicz type of operation may be performed or better cecostomy with end to-end anastomosis later.

In cancer of the *descending colon and sigmoid*, the Mikulicz operation or Rankin's modification of it has been in great favor, chiefly because of its safety as a one-stage procedure. However, it has many shortcomings. It seldom closes spontaneously so that another operation is generally required for closure because the mucosa soon becomes adherent to the skin thus preventing its closure. In the performance of this operation, one is apt to remove insufficient involved mesentery and, if this occurs, there is transplantation into the abdominal wall which eventually results in open ulceration. Because I have seen many cases end this way, it has discouraged me from its use. To me it seems preferable to do a transverse colostomy and in two weeks, do a clean, radical operation with anastomosis. The colostomy is then closed in about two weeks.

Cancer of the Rectum

When a patient with rectal bleeding presents himself for examination, don't be content with a visual inspection of the anus to determine whether hemorrhoids are present, but do a digital examination and if negative, a proctoscopic examination. You, as well as the patient, will be relieved if a malignancy is not found. Only after this procedure has been carried out should the roentgen examination be done. I know a physician in a community not far from mine who made a reputation years ago because he made the patient take off his coat and vest before examining the chest with a stethoscope. I am sure that you will be amply rewarded if you make this simple routine of digital and proctoscopic examinations for rectal bleeding.

If a lesion is found and you are not certain of its nature, the next question that presents itself is, shall we do a biopsy? That depends entirely upon your experience. In case of any doubt, by all means do a biopsy. I feel that a great deal of harm was done ten or twelve years ago by those who advocated that cancer would be spread by biopsy. Do not be intimidated. Far less harm is done by taking a biopsy than by sitting idly by and watching the cancer grow to such proportions that its margins, elevations, and its craters may even spell the word cancer. Furthermore, a hundred and fifty dollar electrocautery machine is not required to do a biopsy. The scissors, snare, or knife will be sufficient.

The diagnosis having been made and the procedure decided upon, the patient should be told that he has a serious disease which requires immediate surgical attention. I do not think it is fair to minimize the complaint for fear of shocking the patient. I have seen too many of these patients delay operation for months because, just to save his feelings, the doctor told him he had a little ulcer. Naturally, the patient does not see why he has to have a major operation for a little ulcer, so he tries some medicine for a while and, even in this enlightened age, many doctors give medicine for such a lesion.

It is appropriate at this time to speak of gradation of tumors because, when the diagnosis of carcinoma comes back to you, it will be followed with the notation, Grade I, II, III, or IV. Grade I is supposed to be a good cancer, Grade IV a bad cancer. Word seems to have gotten around that cancers of Grades I and II, are to be attacked, but that it is not good cricket to attack Grades III and IV—these should be relegated either to radiation or some other nonsurgical treatment. With this opinion, I wholeheartedly disagree. I am in sympathy with everything that increases our knowledge relative to cancer and I think that grading of tumors is an excellent thing from an academic standpoint, but I am distinctly opposed to guiding therapeutic effort merely on

a pathologist's statement that this is grade so and so. At the present time, clinical judgment surpasses any laboratory test so far as the decision of treatment is concerned. The shortcomings of the grading of tumors as a criterion for the treatment to be used are too numerous to mention here. If a cancer of the rectum is clinically operable, operate regardless of whether it is Grade I or Grade IV and you will be doing the best thing for your patient.

The treatment having been decided upon, the patient should be encouraged to enter the hospital as soon as possible. Here, further investigations should be carried out and on the thoroughness of these examinations and adequate preoperative care depend the success of the operation. A thorough physical examination is essential. Studies of blood chemistry and tests of kidney function are important in order to ascertain the risks. In all men over sixty years of age, if they have any urinary disturbance whatsoever, a cystoscopic examination is necessary because of the possibility of associated prostatic hypertrophy which may prove disastrous if not recognized. In many of our patients, it has been necessary to do a resection of the prostate either before or after resection of the rectum. During the stay in the hospital, a high calorie, nonresidue diet is given. Glucose intravenously is administered to build up the glycogen reserve of the liver because many of the patients have been dieting for some time on account of bowel disturbance, the chief symptom of which has been diarrhea. This is not a true diarrhea, however, rather it is the frequent emission of pus, mucus, and blood from the ulcerated area. As a matter of fact in most cases of so-called diarrhea, the colon is filled with hard, dry feces and many days are required to empty the colon. For this purpose we give magnesium sulphate daily in divided doses for five or six days prior to operation. By this measure, it is felt that we can decompress the bowel in all cases of chronic obstruction just as well as by preliminary colostomy.

In the preoperative treatment the question of intraperitoneal vaccine naturally comes under discussion. I have never been impressed with its value when dealing with cancer of the rectum because peritonitis as a cause of death has played a minor rôle in our series of cases. To inject vaccine routinely in a large number of cases seems to me an unwarranted procedure. It must be remembered that the use of vaccine does not, by any means, eliminate peritonitis. It has been reported to lower the incidence. Meticulous technique is still far more important than intraperitoneal vaccine in its present form.

Operations for carcinoma in the various segments of the colon have been fairly well standardized but there is considerable discussion regarding those for the rectum and rectosigmoid. Many different types of operation are advocated. The chief reason for this is the controversy over the undesirability of the colostomy. Posterior resection with perineal anus still has its supporters and many different varieties of operations have been designed. Now, other types of segmental resection are being tried anew. However, one has only to look over the records of older, just as able surgeons and from them these facts are learned—viz., that the operability was low, the mortality high, and the curability rate low. Such is the story from smaller operations or operations devised to save the sphincter. I am not one who believes in the statement handed down from textbook to textbook that cancer of the rectum is different from cancer elsewhere, that it tends to remain localized for long periods of time, and that glandular involvement occurs late. If that were true, why has the curability rate been so miserably low?

Cancer of the rectum and rectosigmoid demands just as radical a procedure as does cancer of the breast if we are to improve our curability rate—and radicalism from the standpoint of the rectum is best attained by the combined abdomino-perineal operation which was described by Miles⁴ of London and which should bear his name regardless of a few varia-

tions in technique described by different operators.

This operation may be done in one or two stages and a surgeon must use that with which he is most familiar and which is best suited to the available facilities at his command. The name "two-stage" obviously carries with it the implication of the factor of safety but this does not necessarily follow. It must be remembered that, when two major procedures are performed on persons in this age group, the hazards of accidental death are increased beyond our control by two times. Emboli, pneumonia, and unexplained sudden death are a source of annoyance to all of us.

Then again, many things may happen during the first stage which may delay the second operation for a long time or may give rise to complications which may lead to abandonment of the second stage, such as pneumonia with empyema, severe infection of the abdominal wall, or phlebitis.

In addition, technical difficulties are encountered in the second stage which do not pertain to the one stage. Finally, the combined mortalities from the first and second stage will be greater than from the one-stage. For these many reasons, I personally have favored the one-stage procedure because, in a series of more than 350 cases, the mortality has been under ten per cent.

After preoperative preparation which averages about seven days and to which I attribute no little amount of success, anesthesia is the next thing of importance to be considered. I still favor spinal anesthesia because it induces relaxation and a quiet abdomen which lends itself to a more rapid performance of the operation. The deep Trendelenburg position is invaluable on account of the deep pelvic dissection which is necessary. The abdominal part of the operation consists of about nine simple, straightforward maneuvers which, if carried out methodically, simplify an otherwise laborious, time-consuming task. The perineal part of the operation is expeditiously done provided the abdominal dissection has been

thorough, otherwise, it likewise will be too time-consuming

Blood transfusion is routine either before or after operation, sometimes before and after, depending upon the condition of the patient. Postoperative treatment is symptomatic

The colostomy is opened on the second or third postoperative day depending upon the gas pains the patient experiences. The wound is protected with vaseline gauze over which rubber tissue is placed. I feel that infected wounds occur at the time of operation and are not caused by early opening of the colostomy, provided ordinary care is exercised. About ten days after operation, the colostomy is trimmed down to about one-quarter of an inch above the level of the skin so that the healed wound is just about at the skin level or slightly above it.

In the last 200 cases, we have been bringing the colostomy out at the midline and have found it infinitely better from many standpoints. *First*, it saves time during the operative procedure, *second*, if a colostomy bag is worn, the patient looks symmetrical and not lopsided as is the case with the inguinal colostomy. This is very important in the care of the woman patient. Again, if an inguinal colostomy is used and the patient wears a colostomy bag, it generally rubs the crest of the ilium which leads to irritation and also leakage in case of accident due to improper fitting.

The care of the bladder is very important in these cases. Since extensive pelvic dissection is required, many sympathetic nerve fibers which innervate the bladder are destroyed and about seventy-five per cent of the patients will have some bladder disturbance for a month or two. Formerly we used a retention catheter for six or seven days but experience has taught us that it is better to catheterize the bladder three or four times a day, which practice has resulted in fewer complications. From twenty-five to thirty per cent of the patients will void spontaneously and cystitis will be avoided in at least this number, whereas it might have been contracted had a re-

tention catheter been left in place. In only one instance have we had permanent damage to the bladder and that occurred in a case where it was necessary to remove part of the prostate due to fixation. Probably the sphincter itself was interfered with here. Urinary antiseptics and frequent irrigations of the bladder are used to treat the infected bladder.

The rubber dam and gauze pack employed to support the new pelvic floor and prevent oozing at the time of operation are removed partly on the second, third, and fourth postoperative days, after which the cavity is irrigated with saline solution or sterile water until most of the discharge has subsided. After this, it is merely swabbed out with cotton pledgets. This is a simple procedure which is taught to some member of the family when the patient is discharged, for ten to twelve weeks are required for this posterior wound to fill in.

In a normal convalescence, the patient is allowed out of bed in twelve to fourteen days. This permits the new peritoneal pelvic floor to sag a little and thereby hastens the obliteration of this large cavity.

The performance of a successful operation does not mean, however, that the surgeon's obligation has been fulfilled. He must take time to instruct the patient regarding the care of the colostomy and on this instruction depends the happiness of the patient. The usual instruction is to tell the patient to go to a surgical supply house and buy a colostomy bag. That is a sure way to make him a social outcast. The odor from the rubber is far worse than the odor of the stool. Personally, in my preliminary instruction, I do not even mention that there is such a thing as a colostomy bag. The patient is taught to irrigate the colostomy himself, not to have some member of the family do it because this is always embarrassing to the patient. Many good types of apparatus are on the market, the only objection to them being the cost. All that is necessary is the ordinary enema apparatus with a little rubber disk on the enema tip which, when placed tightly against

the colostomy, will make it water tight

Experience has taught us that daily irrigations are too frequent. The colon will be kept too clean and soon the patient will complain that he cannot get his bowels to move. We have found it best to irrigate every second day and in a few months, if this routine is carried out at the same time, the bowel will become practically an automaton

Accidents between irrigations rarely occur and patients wear only a small pad under an abdominal binder suited to their individual tastes. Our instructions and demonstrations regarding the care of the colostomy are more time-consuming than the performance of the operation itself

I have never been impressed with the desirability of giving the patient a constipating diet. Such a diet may cause diarrhea in another patient, so I tell them to follow the diet they have been accustomed to and eliminate from time to time such things as disagree with them

The question of postoperative radiation is always a pertinent one. If the proper operation has been performed, there will be nothing left in the pelvis except small intestines, and I do not think it is a good policy to radiate them routinely

In this group, we have operated on patients in an age range from twenty six to seventy four years. Five per cent of our patients have been seventy or over, and the mortality in this group is the same relatively as in the other age groups. Age alone is not a contraindication to operation. Many patients at seventy are better risks than some at sixty but I do think that good kidney function is essential in patients over seventy. Hypertension, arteriosclerosis, diabetes, and obesity have not deterred us from the performance of this operation

Palliative operations are essential in a certain group of inoperable cases. Some patients are not benefited a great deal by colostomy, and it is important to study these carefully and make a distinction between the pain of obstruction and the pain of metastasis. Routine colostomy in the latter group will only add to the patient's misery and, in my estimation, is contra-indicated unless there is obstruction

Operability percentage is always of great interest and, with this in mind, I reviewed one hundred consecutive cases of cancer of the rectum as the patients presented themselves for examination beginning July 1, 1937 and going back until 100 consecutive cases had been reviewed. Table 1 is quite informative and gives one a comprehensive picture of what happens in a definite group

EXPLOSION RISKS AT OPERATIONS

The danger of explosions in the operating room resulting from a union of static electricity in the atmosphere and anesthetic mixtures has been eliminated largely as the result of a new device which determines the exact amount of static electricity present it is reported by Dr

Horatio B. Williams, before the Congress of Anesthetists in New York City

When the new device shows that a dangerous amount of static electricity is in the air more humidity which counteracts the electricity is pumped into the operating room by ventilation and water vapor

Introduction

This outline is a résumé of the methods which the author has found from his own experience to be the most effective in the treatment of syphilis. The methods are in the main those worked out in the Department of Dermatology of the Vanderbilt Clinic. The conclusions presented were reached after many trials of different drugs, dosages, and systems of treatment, extending over a period of more than twenty years. No responsibility is assumed for reviewing methods in use in other treatment centers, in this country or elsewhere.

Although treatment alone is discussed here, it goes without saying that a diagnosis of syphilis must be definitely established before a patient is permitted to embark upon any course of antiluetic

treatment. Every patient, on his first visit, is given a thorough physical and neurologic examination. Usually a cardiogram also is taken at this time. In every case suspected of being early syphilis, the clinical diagnosis must be confirmed by a laboratory diagnosis—either a positive Wassermann confirmed by a second test, or the demonstration of *Treponema pallidum* in the secretion taken from the initial lesion, or from a skin papule or a gland puncture.

Once the diagnosis is established, the patient should be given instructions in regard to diet, rest, exercise, and personal hygiene. Patients with early syphilis in particular should be warned to take precautions against infecting others. If the patient is married, the wife or husband and any minor children should be exam-

From the College of Physicians and Surgeons of Columbia University, New York City

med In case of extra marital exposure, an effort should be made to induce the patient to send his partner to a physician

Every patient should have explained to him the nature of his disease, the necessity for regular treatment over a considerable period of time, and the importance of a follow up at regular intervals after the completion of the prescribed treatment. He should not be left with the illusion that the clearing up of external lesions or the first negative blood test indicates a cure, but he may be reassured that his chances of an ultimate cure are at a maximum if he follows faithfully the plan of treatment outlined for him by his physician

It is recommended that the physician, having studied his case and established his diagnosis, make out in advance for the year a scheme of treatment suited to the needs of his patient. If the patient is a young healthy adult with early syphilis, the physician will do well to follow one of the routine plans of treatment outlined in the following pages. If the patient is in a more advanced stage of the disease, or if allowance must be made for age or constitutional disability, a plan is equally important, but it must be adjusted to individual requirements. In this way the physician will avoid the responsibility for haphazard and desultory treatment which has given evidence of being worse than none at all

It is not claimed that this is the last word in antiluetic therapy. I believe that we are still far from having an ideal treatment plan, and that continued study and experiment will make possible many improvements. The following plan is submitted because it represents the best that we have been able to devise up to the present moment.

I freely acknowledge my obligation to colleagues in this and other institutions with which I am or have been connected, particularly to members of my staff at the Vanderbilt Clinic, whose cooperation has made possible a more comprehensive trial of drugs and methods than would have been otherwise possible.

When and How to Treat General Instructions

Beginning Treatment—Without question the most gratifying rewards are to be had when treatment is begun within the first year of a syphilitic infection. The patient can quickly be rendered non-infectious—the most important consideration from the standpoint of public health, and since most patients with freshly acquired syphilis are young healthy adults, it is usually possible to carry out a regular plan of vigorous and thorough treatment, which provides the maximum chance for a cure with a minimum of risk. This early treatment is the surest preventive of the disabling forms of late syphilis, involving the cardiovascular and nervous systems. When once these vital structures have been damaged, treatment must be largely palliative, and limited to checking further advances of the parasite. In studies of early syphilis, our own records have shown that the highest percentage of satisfactory results (over 90 per cent) were secured among patients whose infection was diagnosed from the primary lesion and the presence of *Treponema pallidum*, and who began treatment immediately, before the blood Wassermann had become positive. Patients with primary sores and a positive Wassermann but with no secondary skin manifestations as yet, achieved the next highest percentage of satisfactory results, while patients whose treatment was not begun until a secondary eruption had appeared showed the least satisfactory response among the early cases.

Continuous vs Intermittent Treatment—Comparison of results achieved both in this clinic and elsewhere, under different systems of treatment, has amply demonstrated the superiority of continuous over intermittent treatment. The ideal is to keep the patient at all times under the influence of either arsphenamine or a heavy metal, and during the initial attack, in early syphilis, it is an additional advantage if both arsphenamine and the heavy metal courses can be given concurrently, thereafter they may alternate

or overlap When the patient is receiving only the heavy metal he should also be given potassium iodide by mouth No "rest periods" should be prescribed in early syphilis, if the patient must miss treatment, as for example, when traveling, he should take mixed treatment by mouth, or mercury rubs, or arrangements should be made with a local physician or clinic to continue the treatment which has already been initiated

The Choice of Drugs—Of all anti-syphilitic remedies so far tried, the arsphenamines are generally acknowledged by syphilologists to be the most active of those tolerated in therapeutic doses Of the arsphenamine series, the one which has maintained its superiority so far against all newcomers is old arsphenamine, or simply "arsphenamine," originally elaborated by Ehrlich as "salvarsan" or "606" (known also in France and England as "arsenobenzol" or "arsenobillon") In our comparative studies of old, silver, and neo-arsphenamine, old arsphenamine was shown to bring about the healing of lesions and the reduction of a positive Wassermann to negative in a shorter time and with a smaller amount of the drug than did either neo- or silver arsphenamine There were also fewer relapses and a higher percentage of satisfactory end results in our series under old arsphenamine than under either of the other arsphenamines tried, and despite much prejudice to the contrary, there were fewer serious reactions following its use

Silver arsphenamine (arsenic 19 to 20 per cent, silver 12 to 14 per cent) has proved useful as a substitute for old arsphenamine in certain cases where the latter is not well tolerated, or where there is a suspicion of drug-fastness Neo-arsphenamine and sulpharsphenamine we do not recommend, we have found them too toxic when given in doses high enough to be therapeutically active, and we consider fallacious the argument that the lower therapeutic value of these preparations can be offset by giving larger doses

Concerning bismuth and mercury, our fairly extensive comparative trials of different preparations of the two metals

have not disclosed any striking advantage of one group over the other, except the lower incidence of immediate ill effects under bismuth (but bismuth seemed to contribute to more delayed reactions than did mercury) Both are valuable adjuncts to arsphenamine, but neither should be expected to replace arsphenamine, except of necessity in cases where an arsphenamine is definitely contraindicated The preparations recommended in this outline are limited to those actually tried out in this clinic and found generally satisfactory

Dosage—The dosage recommended in the following treatment schedules is intended for the patient of average weight and generally sound physique, and should, of course, be modified when necessary, to suit the individual case It is often advocated that the dosage be based on body weight (0.05 Gm to 0.1 Gm of arsphenamine per 25 pounds) I do not believe that dosage should be determined by arbitrary standards of either weight or age A strong muscular active individual of 145 pounds with healthy excretory mechanism will be able to tolerate a higher dose than a 200-pound subject who is fat, flabby and inactive, and has sluggish excretion Likewise a healthy, well-developed child of fourteen may easily tolerate more of the drug than a poorly nourished, anemic adult.

It will be noted that the total dosage of the arsphenamine course is increased as the injections are more widely spaced This increase, however, is subject to rather narrow limitations, because of the danger of exceeding the patient's tolerance This needs to be taken into account particularly during the first few injections of a course For this reason I consider that 0.2 Gm or 0.25 Gm given twice a week is better than double the amount given once a week Even when obliged to give the treatment once a week throughout the course, the physician will find it safer to begin with the smaller doses and increase them during the latter half of the course

For modifications in dosage and other particulars of treatment for elderly pa-

[illegible]

Fig 1 —Outline of treatment for early syphilis

tients, those in the later stages of syphilis, and those with constitutional disabilities of various kinds, also for special dosages for children and pregnant women, see under appropriate topics

Treatment Schedules—The plan for the treatment of early syphilis forms the backbone of any treatment system. Hence plans outlined here for other stages of the disease may properly be considered simply as modifications of this basic outline for treatment.

For patients with primary or secondary syphilis one year of regular and continuous treatment is recommended, as follows: a total of three courses, of ten injections each of an arsphenamine, preferably old arsphenamine, and three courses of fifteen injections each of a mercury or bismuth preparation. During the first month the arsphenamine and mercury or bismuth courses run concurrently, thereafter they alternate or overlap, so that the patient is continuously under treatment with one or the other or both.

The preferred (3-2") plan calls for three arsphenamine injections a week for the first six injections, the remaining four injections to be given at 3, 4-, 5-, and 6-day intervals to complete the first course. In the second and subsequent courses the first six injections should be given twice a week and the following four, weekly.

An alternate ("2-1") plan may be substituted for patients who must attend less frequently. Thus calls for two arsphenamine injections a week for the first six injections, and the following four at weekly intervals. In the second and subsequent courses, give one injection per week throughout the course. In this plan, the dosage is slightly increased to compensate for the wider spacing of injections.

The *Treatment Chart* reproduced on this page represents a compromise between the preferred and alternate plans for the treatment of early syphilis. In clinic practice especially, it is often possible to induce a patient to come at fre-

Four to six weeks interval between 2nd and 3rd arspenamine courses

Third arspenamine course Repeat dosage and intervals of 2nd course

Arspenamine should total 30 injections (3 courses of 10 injections each) in the first year

As soon as second arspenamine course is completed, resume mercury or bismuth and give two more courses of 15 injections each, at weekly intervals, dosage as above

Mercury or bismuth should total 45 injections (3 courses of 15 injections each) in the first year

* Dosage based on mercury salicylate.

† Dosage based on preparations containing 50 mg of elemental bismuth in 1 cc.

quent intervals during the first course, but difficult or impossible to keep him coming oftener than once a week during subsequent courses. The interval between the first and second courses of arsphenamine should be four weeks, between subsequent courses, six weeks.

The first course of fifteen injections of mercury or bismuth is given at four- or five-day intervals for the first six injections and weekly for the following injections of the course. Both intravenous and intramuscular injections may be given at the same visit for the convenience of the patient, except that during the first two weeks the patient receives four to six injections of arsphenamine and only three or four of mercury or bismuth. Between arsphenamine courses and while the patient is receiving only the heavy metal he is also given potassium iodide by mouth. A urinalysis should be done every one or two weeks and a complete blood count as well as a bile index should be taken once a month. For deviations from normal, see "Prevention of Reactions to Arsphenamine," and "Complications Due to Bismuth and Mercury."* A test of the spinal fluid should be performed at the end of the first year, and preferably also at the end of the first course of treatment.

Outline of Treatment for Syphilis in Pregnant Women

When a pregnant woman is found to have syphilis, treatment must be directed primarily toward securing a healthy infant. The possibility of delivering a healthy infant is in direct proportion to the promptness with which antiluetic treatment is instituted, and the thoroughness with which it is carried out. If infection has taken place at or around the time of conception, and treatment is begun within the first month and continued throughout the pregnancy, the chances of securing a healthy full term infant are practically as good as for the nonsyphilitic woman. If treatment is delayed until after the fifth month, the chances for a healthy infant are slight.

For the pregnant woman with early syphilis, the best plan is to follow through the routine treatment for early syphilis, making whatever modification may be necessary to give the last arsphenamine course—or as much of it as possible—just preceding delivery.

For the pregnant woman with tertiary or latent syphilis, follow the special plan outlined here, arranging, if possible, to give an arsphenamine course just preceding delivery. The pregnant syphilitic woman who is under such serious constitutional

As soon as arsphenamine course is completed, resume mercury or bismuth with iodides, and continue alternating courses of arsphenamine with mercury or bismuth for at least one year with dosage and intervals as indicated above.

All tertiary cases should have, at the first visit, in addition to complete physical and neurological examination, tests of both blood and spinal fluid. No arsphenamine should be given to persons over 50 years of age unless stage of disease requires it and general physical condition permits it.

* Dosage based on mercury salicylate.

† Dosage based on preparations representing 50 mg. of elemental bismuth in 1 cc.

* To be published in the next issue

disability—either from syphilis or some other cause—that she cannot tolerate antiluetic treatment adequate to insure a healthy infant, should have her pregnancy interrupted

For women who have been thoroughly and adequately treated for syphilis prior to the pregnancy in question, whose Wassermann has remained consistently negative, and who for practical purposes are considered cured, I can see nothing to be gained by treatment throughout pregnancy. The Wassermann should be taken frequently (once a month is advisable) and at any appearance of a positive serology, or if there is for any other reason a doubt about the patient's "cure," it is better to play safe by treating as in known cases of syphilis. The husband, if infected, should, of course, have received thorough treatment, and be clinically and serologically negative.

Resumption of Treatment after Delivery—Treatment as outlined may be resumed within two or three weeks after delivery. It is of special advantage to the infant for nursing mothers to receive treatment, as arsenic has been shown to appear in the milk of mothers receiving arsphenamine treatment. Treatment should be continued until at least the minimum required amount has been given, or for at least six months after the blood Wassermann has become negative.

For early syphilis in pregnant women use the same treatment as for nonpregnant women. For tertiary and latent syphilis treat as shown at bottom of page.

Special Precautions—Before each injection, take blood pressure and test

urine for albumen. If blood pressure is above 150, or if urine shows heavy trace of albumen, withhold injection, have complete urinalysis and blood chemistry done, and direct patient to obstetrician. A gradually increasing blood pressure, even though still below 150, should be regarded with suspicion, and the patient should be closely questioned for signs of excessive nervousness and reactions of all kinds, in order to prevent eclampsia.

Treatment for Children of Syphilitic Mothers—See "Treatment of Congenital Syphilis."

Outline of Treatment for Congenital Syphilis

Children of syphilitic mothers are not treated unless the child has two or more positive Wassermanns, or a Wassermann supported by one or more precipitation tests, or unless the child has clinical manifestations of syphilis. Tests are made from the cord blood of the infant at birth, from the infant's blood at six weeks, three months, six months, and annually up to three or four years. Ideally, it would be better to repeat the test annually until the age of puberty. Late manifestations will nearly always have made their appearance by this time. If a positive serology is found at any time, and is confirmed by a second test, treatment is begun immediately.

Choice of Drugs and Methods—Syphilis in infants and children is treated in the main like syphilis in adults, except for the modifications in dosage and technic explained hereinafter.

Arsphenamine is the drug of choice, to

be supplemented by the heavy metals as in the treatment of adults. Where arm veins are difficult to enter, one may use ankle veins or jugular or scalp veins. In the latter case, place rubber band or tourniquet around base of skull to make veins stand out. If the operator is not sufficiently skilled in giving arsphenamine intravenously to infants, it is permissible to give it intramuscularly in concentrations of 1 to 2 cc. per decigram, following the usual dosage for infants, and observing the technic outlined for the administration of the heavy metals. It should be stressed that freedom from reactions to intramuscular injections of arsphenamine will be in direct proportion to the thoroughness with which the parts are massaged after the injection.

Bismarsen (bismuth arsphenamine sulphate, bismuth sulpharsphenamine). If an infant proves intolerant to arsphenamine one may give bismarsen intramuscularly (never intravenously). This preparation probably stands somewhere between arsphenamine and the heavy metals in therapeutic efficacy. We have never found it necessary to use this or other arsphenamine substitutes for infants in this clinic.

Neoarsphenamine we have found to

have low therapeutic efficacy coupled with high toxicity, and when given intramuscularly causes just as much local discomfort as arsphenamine.

Sulpharsphenamine (except in the form of hismarsen) we do not advocate, believing it to be less effective than the other arsphenamines and far more toxic.

Bismuth and mercury should be given as usual to supplement arsphenamine courses, with modifications of dosage according to the following schedules. In poorly developed and undernourished infants or those in a lowered state of vitality at birth, it is advisable to give injections of a heavy metal only, or even mercury injections alone, until the child becomes stronger.

Fever Therapy—Since in congenital syphilis, especially in the late forms, it is difficult and frequently impossible to obtain a negative Wassermann, it may be advisable to give fever treatment, either malaria, fever box, or typhoid vaccine, in cases which have failed to respond to the usual treatment continued over two years or more, and also in cases of interstitial keratitis after the acute stage has passed.

[To be continued in the next issue.]

A novel plea was made by a California chiropractor arrested for speeding. He urged that instead of being fined for going one mile at 60 his miles should be averaged and the result

would be found well within the law. When this was refused, he offered to pay his fine in treatments for the judge. This was also firmly declined.

Society Activities

Changes in Group Plan Rates and Coverage for Malpractice Insurance

Important and valuable modifications in both the rates and coverage of the State Society's Group Plan of malpractice defense and indemnity have been reported by the Insurance Committee and accepted by the Council at its November meeting. These changes were foreshadowed three years ago when the master policy was transferred to the Yorkshire Indemnity Company of New York. At that time the carrier had demanded an increase in rates which the Society was unwilling to approve, believing that it was not justified by the experience under the terms of the carrying agreement existing between the Society and the company. In addition to avoiding what the Society believed to be an unwarranted rate increase, it was desired to redraft the coverage so as to provide members with protection on account of the acts of temporary substitutes which prior thereto had never been available. Also, it was felt necessary to revise the cost accounting system so as to furnish a more accurate and satisfactory method of determining cost and computing rates in the future.

The transfer was approved by the House of Delegates and put into effect January 1, 1936. Now after three years of operation under the new arrangement, the Society is able to announce a reduction on all rates and a broader form of coverage. Since, during these three years, there has been no diminution in the number or cost of suits and claims chargeable to the Group Plan, the wisdom of the transfer is fully demonstrated.

The changes will apply to all new certificates and to renewals dated on and after January 1, 1939. They represent concrete benefits for all members and are as follows:

1 The base rate has been reduced to \$28 00.

- 2 A sliding scale of reduction has been made in rates for all limits of insurance in excess of the minimum.
- 3 The surcharge for x-ray therapy has been reduced from \$40 00 to \$30 00, making a minimum rate to include that specialty \$58 00 instead of \$70 00 as heretofore.
- 4 Members desiring protection on account of x-ray therapy ONLY may now have their certificates so endorsed and issued at the surcharge rate only.
- 5 Protection on account of temporary substitutes, permanent assistants, and licensed or specially qualified technicians has been included in the base policy without additional charge, provided that medical substitutes and assistants are members of the State Medical Society and individually insured under its master policy.
- 6 Limit No 1 in the amount of insurance has been changed to apply to any one suit or claim regardless of the number growing out of any one cause or action. This is a return to the former provision of the policy contract.
- 7 The exclusions on account of unlawful acts have been combined in one paragraph and the wording changed so as to indicate clearly that they apply only when it has been established that an unlawful act has been committed and not to a mere allegation of such an act. This has always been the intent and it has always been so construed, therefore, this change is only a clarification of phraseology.

8. The exclusion on account of the use of x ray therapy has been extended to include the detailed prescription of x ray therapy dosage for some other person to carry out.
9. Heretofore, the policy, as it applies to any one Assured, has been noncancellable except for non payment of premium or failure of an Assured to maintain in good standing his membership in the State Society. In addition, there has been added a provision that a certificate may be cancelled at any time at the request of the Assured upon the customary short rate basis.

The importance of these changes is far reaching and promises well for the future. The rate reductions alone will save nearly \$40,000 a year in the bill which members pay for malpractice indemnity and defense. It may be more important, however, to stress the point that members will now be able to increase the amount of their protection under a broader form of coverage without increase in cost. This view will not escape the consideration of prudent members who have watched with apprehension the growing size of suits and the tendency of all juries to return higher verdicts.

It is sometimes asked why the Society has a Group Plan of indemnity and defense and why members are not encouraged to buy their protection as individuals from any company willing to insure them. The older members know the answer to that, of course. But next May the Group Plan will be eighteen years old and during those years a whole generation of men and women have grown up and come into the practice of medicine, having no knowledge whatever of the chaotic conditions immediately following the war which finally impelled the State Society to take command of the situation in this state. So, for the benefit of the younger members coming into the Society, this question should be answered clearly at least once every year.

Briefly stated, the system of individual buying of malpractice protection from freely competing insurance companies and having to deal individually with those companies, proved a complete failure in New York State after a long and untrammelled test. It failed to provide doctors with competent and satisfactory legal defense. It failed to maintain the cost of indemnity and defense within the reach of the average member. It failed to provide a united and effective check to the constantly increasing threat of malpractice claims. And it denied organized medicine an opportunity to exert its influence upon the trend of events or to intervene with the companies when necessary to protect the interest of its members.

Medical men had learned from bitter experience that, in a malpractice action, expert legal defense for the protection of their professional standing and reputation in their communities is usually far more important than the amount of money at stake. While the insurance companies had the facilities for supplying indemnity none of them had attorneys with sufficient medicolegal experience or possessing enough knowledge of medicine or its practice to furnish expert and competent defense. On the other hand, the State Society has developed the most expert and successful legal defense to be found any place in the country, but had no facilities for supplying indemnity. Obviously some plan for bringing these two services together in one undertaking was the logical solution.

The Society took the initiative and worked out all of the details of such a combination to be operated under the supervision and control of the Society. It became known as the Society's Group Plan of Malpractice Indemnity and Defense and was put into operation on May 10, 1921. It was a unique, astute, and timely action which immediately cured the intolerable conditions which existed at that time and has prevented a return of them.

During the years which have intervened since its organization, it has supplied,

through the legal counsel of the Society the most competent and able legal defense available in the country. It has prevented high rates, and saved members a total of over a million and a half in premiums for minimum policies alone. It has provided a united front to combat unjust malpractice suits or claims and is effectually educating the suing public and its attorneys to the understanding that they must have sound and honest claims before they can hope to translate them into money damages through the courts. In fact, without this united front no company would or could afford to insure the members of the State Society. Last but not least, it has helped to support and has made possible the continuance of

free malpractice defense of uninsured members. Certainly no activity of the Society is more worthy of the active support of every member.

In publishing to the Society the new rates and coverage which will be available beginning January 1, a word of appreciation should be said on behalf of the Yorkshire Indemnity officials whose co-operation and assistance have made the changes possible.

THE ANSWER TO THE DOCTOR'S PRAYER

Unfortunately, too many addresses at medical meetings are of little practical value to the physician in his daily practice, thinks the *Ohio State Medical Journal*.

A physician who takes time off from his practice or gives up an evening at home to attend a medical meeting does not want to hear an ultra-scientific paper, hurriedly read. He wants a well-prepared practical talk, delivered informally and interestingly and comprised of understandable terms. In other words he wants to hear something which will stay with him and give him suggestions he can use in his daily practice. He wants authoritative, up-to-date information, based on the speaker's experience, which will make his diagnosis more accurate and his treatment more effective. Of course, there is a place for the highly technical treatise on recent experiments and unusual cases, but that place is in the literature where it can be read and digested during leisure moments.

The speaker who "huts 'em between the eyes" with something practical, stripped of a top-coat of big and unnecessary words and phrases, is the chap who answers the average doctor's prayer.

Patient "I have an awful rumbling in my stomach, Doctor."

Doctor "Hmml. Probably that truck you ate last night."

—Wichita Med Bulletin

PENALTIES OF FEMINIST MUTINY

In Australia thirty-one per cent of all first births are the result of extramarital conception. Also, during the last twenty years, says a report in the *Journal of the A M A*, the percentage of deaths from illegal operations has been multiplied by four, it now represents twenty per cent of total maternal deaths. These facts point to a loosening of moral standards, with consequent increase in intemperate contraception and criminal abortion for the failure of contraception. Intemperate contraception and criminal abortion have destroyed and are destroying the health of thousands of women. In the opinion of Dr. McLelland man is the defaulter. He considers that the feminist movement was a frank mutiny conditioned by man's failure in the primary duty of sustenance and protection of woman. The increasing extent to which women are employed in industry and commerce, the increasingly high wages paid to women and their insistent demands for independence, and the consequent unwillingness of young women in employment to enter matrimony are important factors in the increase of abortion. Added to these is the changed attitude of men toward women.

A doctor received this note:

"Please call and see my husband. It's his head. He's had it off and on all yesterday, and today he's sitting with it in his hands between his knees."

—Montreal Star

The Woman's Auxiliary

To the Medical Society of the State of New York

QUESTIONS and answers appear to be the order of the day. Individuals, the press, the radio, and the mail, each contributes its share.

Why are you an Auxiliary member?

How does the Auxiliary function?

What are the purposes of the Auxiliary?

What are the Auxiliary's policies, plans, and activities?

What is necessary for the Auxiliary's progress and growth?

These are but a few of the questions to which we endeavor to reply.

While ever vigilant of the trend of affairs, traditions and ancient philosophies still guide and inspire us. "Know thyself," a slogan of the early Greeks, continues to be as applicable now as then. It might well be adopted as our own, so completely does it serve. More than the study of self, such introspection would disclose our power and our abilities.

The appreciation of which appears as the initial step toward the achievement of the Auxiliary's aims and purposes. Comprehending these qualities, confusion in the minds of many would disappear, along with their apparent lethargy. There being no further inquiries about the functions of the Auxiliary, every doctor's wife would welcome the opportunity of taking part in a program of health education. Extending the aims of the medical profession to all other organizations interested in health education is a big endeavor and necessarily must be carried on only under advisement.

The activities of the Auxiliary encompass every phase of woman's organization work and are therefore of interest to all. Health education, legislation, public relations, philanthropic, and social, each has a part and in turn holds the attention.

While we are the natural allies of the medical profession, to be worthy representatives self-education must play a major rôle.

As we are active in our various community organizations, we can serve best by guiding and directing the health programs of these groups. It is here that the Speakers Bureau of the Medical Society assists. Public Health Institutes and health programs given by the Auxiliary have proved of interest to the laymen. Active participation in many health matters such as maternal welfare, cancer control, and the fight to control tuberculosis have kept the Auxiliary occupied.

The promotion of *Hygeia* is urged, since it is an official and authentic health publication, readily understood by all. It is apparent that it is the most valuable weapon with which to combat cultist propaganda. These are mentioned as but a few of the Auxiliary's health interests.

Studying the legislative program of the Medical Society has kept the Auxiliary abreast of all legislation affecting the public health and medical profession. While always alert, no action is ever taken, unless it is requested. Legislation is a common denomination of all interests and occupies a prominent part of our concern.

Each community supplies its own philanthropic needs and problems, along with those of larger appeal. With the seriousness of our objectives, the social side is never neglected. The gains of friendliness and good fellowship are most in valuable aids.

The universal plea for understanding interest and co-operation is also the Auxiliary's. These are vital factors, necessary to progress and growth. A large membership, for its numerical

value alone, holds no interest, save as a necessary medium to successful achievement

There is no wish to break with tradition, but rather do we strive to uphold it. It is evident that the economics of yesterday is not today's, nor will it hold for tomorrow. What then is more natural than the desire to help preserve our hearth and economic future?

It is to the County Auxiliary to whom we must look for the visual means whereby the steady growth of the whole may be maintained.

As we carry on with our unselfish endeavors, remember always, we are but an Auxiliary.

County News

Albany A meeting of the Woman's Auxiliary was held on Tuesday, Nov 30, in the auditorium of the Albany Hospital. The meeting was well attended and the members enjoyed listening to Mrs. Lou Vold, Field Representative of the American Red Cross of Washington, D. C., who spoke on "The Red Cross in Action."

Onondaga Mrs. Winthrop Pennock was elected president and Mrs. Horace

Whitley first vice-president at the annual meeting of the Woman's Auxiliary to the Medical Society of the County of Onondaga held on Tuesday, Dec 6, in the home of Mrs. Frances Irving, Wendell Terrace, Syracuse. Mrs. Catherine Scott Sykes gave a very interesting program of play reviews. A social hour followed the executive session and program.

Queens Mrs. William Lavelle was elected president and Mrs. Raymond Murphy president-elect of the Woman's Auxiliary to the Medical Society of the County of Queens at the annual meeting held on Nov 30, in the Medical Society Building.

Mrs. Kleefield entertained her Executive Board and the new officers at a tea on Dec 6.

Mrs. John Mahoney is chairman of the installation party to be held on Wednesday, Dec 28, 1938, in the Medical Society Building.

Schenectady The Woman's Auxiliary to the Medical Society of the County of Schenectady held a buffet luncheon and bridge at the Mohawk Golf Club on Tuesday, Nov 13.

GETTING DOWN TO BRASS TACKS

The sharp points of some of the brass tacks of socialized medicine are well brought out by Dr. E. Wayne Stratford, of Portland, Oregon, in a letter to *Medical Economics*.

Why, he asks, should medically-trained politicians seek to destroy confidence in private doctors when the indigent sick are sick because of bad diet, dirt, dark houses, and defunct incomes?

Why create medical surveys for investigators who do not know and probably can never know the medical problems to be surveyed?

Why destroy pigs when children of the indigent go without meat because meat is too expensive?

Why rave about incompetent doctors when the children "they are neglectfully treating" are mostly in need of potent cod-liver oil, safe milk, edible eggs, clean meat, and vitamin C?

I see the families of the poor. The children are scorbutic because of lack of oranges, are rachitic because 19¢-a-pint cod-liver oil does not cure rickets, have terrible dental caries because of lack of minerals and vitamins, have colds, flu, sinusities, and scabies because of damp, dark, dirty, stinking homes with inadequate clothing, fuel, food, and baths.

Why should public officials undermine these people's confidence in me when I am the one who will sit down and listen to their plight, get them calcium salts, cod-liver oil, vitamin C, and try to ward off preventable diseases which strike the indigent and help to keep them indigent?

Why publicize the ideas of medical politicians who conceal (or are ignorant of) the true status of medical care of the underprivileged and who throw sand in the newsprint to blind the public in regard to this question?

Medical News

Bronx County

The Bronx County Medical Society will celebrate its twenty fifth anniversary with a dinner, dance, and entertainment at the Waldorf Astoria Hotel on Saturday, Jan 7. The guest of honor will be Dr Nathan B Van Etten, first President of the Bronx County Medical Society, Past President of the State Society, and Past Speaker of the House of Delegates of the A. M. A.

The North Bronx Medical Society met on Dec. 1 at Elsmere Hall and listened to papers by Drs Aaron N Gorelik, Henry Wincor, Solomon Ginsburg, and William Bierman.

Dr Sidney P Schwartz will lecture at the Montefiore Hospital Auditorium on Jan 12 and 19 at 3 30 P M on Electrocardiography.

The lectures are free to physicians and medical students.

Erie County

Dr L Franklin Anderson, chairman of the economics committee of the Medical Society of the County of Erie, declared in a recent report that the 756 active practitioners enrolled in the county society have given to the needy in the past year, without any compensation, medical services representing approximately \$2,532.466.

He listed 33,900 free operations, 3,010 obstetrical deliveries, and approximately 510,000 home and office calls.

It is expected that Buffalo physicians and dentists will receive compensation for treating patients on relief after Jan 1.

The members of the Erie County Society have voted to raise the dues from \$8 to \$10.

Dr Howard B Sprague, of Boston, addressed the Buffalo Academy of Medicine on Dec. 14 on "What Price Coronary Thrombosis?" Dr David E Robertson, of Toronto, addressed the Academy on Dec. 7 on "The Treatment of Infantile Paralysis."

Fulton County

Dr D Ewen Cameron, psychiatrist in chief of the Albany hospital, was guest speaker at the meeting of the Medical Society of Fulton County held on Nov 17 at Hotel Johnstown. "The Insulin and Metrazol Treatment of Dementia Praecox" was the subject of his address. The attendance was the largest of the year.

Kings County

At a meeting of the Ocean Medical Society of Brooklyn on Nov 21, Dr Philip I Nash, president elect of the Kings County Medical Society, who spoke on "The Future of American Medicine," told the 300 surgeons and physicians present that while he does not favor socialization of medicine he recognizes the trends leading to it.

"Investigation leads me to a firm belief that the Government would have to intervene to enable a large mass of indigent people to avail themselves of adequate medical care," he said.

"However, I do oppose any scheme which does not allow patients a free choice of physicians, as this might lead to an opportunity for political meddling."

Dr Frederic E Elliott, former chairman of the economics committee of the New York State Medical Society and proponent of the Elliott plan of co-operative medical care for low-income patients, explained the operation of his plan.

A symposium on pneumonia control was the feature of the meeting of the Medical Society of the County of Kings on Nov 15. The speakers were Drs Wheelan D Sutliff, Tasker Howard, Russell L Cecil, and Richard H Bennett.

Dr J Hamilton Crawford will speak on Jan 11 on "Cardiac Arrhythmias," and on Jan 18 on "Myocardial and Coronary Disease," in Hoagland Laboratory, Long Island College of Medicine, at 4 30 P M. Physicians and medical students are invited.

Livingston County

Dr Edward Windsor Southall, eighty-eight-year-old physician of Geneseo, announces that he is retiring after sixty years of service. Dr Southall believes that walking is the most stimulating and beneficial of exercises and has continued to use that method of travel in visiting his patients.

Madison County

The Madison County Medical Society presented an excellent course of lectures in November and December under the auspices of the Committee on Medical Education of the State Society. The topics and speakers: "Scarlet Fever," by Dr A C Silverman, Syracuse, "Anemia," by Dr K R McAlpin, New York City, "Asthma," by Dr Albert Vander Veer, New York City, "Nephritis," by Dr J D Lyttle, New York City, and "Diabetes Mellitus," by Dr David D Moore, New York City.

Monroe County

United efforts by physicians and pharmacists to end "useless and frequently harmful consumption of drugs" by glib Americans who spend \$360,000,000 a year on self-medication were urged by Dean A B Lemon of the School of Pharmacy, University of Buffalo, on Nov 15, at a joint meeting of the Monroe County Medical Society and the Rochester Pharmaceutical Association in the Rochester Academy of Medicine. Dean Lemon declared that 20 per cent of the nation's adult population attempts self-diagnosis of illness and practices home treatment with patent medicines.

He claimed that organized pharmacists were squarely behind any movement to stamp out the practice, and advised a continuous program of education and restrictive legislation "to save the public from their own folly."

Monroe County doctors and pharmacists also viewed a sound motion picture at the Nov 15 meeting, illustrating the work of the Army Medical Service in war time, and the Maternal Mortality Analy-

sis Committee discussed "A Review of Maternal Death Case Records."

Medical, civic, industrial, and religious leaders in Monroe County are contemplating the advisability of setting up a "Non-profit Medical Expense Indemnity Insurance Association," a plan for wage-earners, as stated by the County Medical Society, "wherein an individual, by making payments of stated premiums, makes available to himself a definite sum of money for the payment of his physician's charges for professional service."

Dr Alva P Maine, 92, of Webster, whose birthdays have been celebrated by a town clambake for the past nineteen years, died on Nov 7.

Nassau County

More than three hundred physicians, dentists, and teachers listened to an address by Dr Hiram A Jones, of the State Department of Education, at Hempstead on Nov 21, on the subject of school health. Dr Louis H Bauer, President of the Medical Society of Nassau County and of the Second District Medical Society, also spoke in the discussion.

Surgery was the topic at the meeting of the Medical Society of Nassau County at Mineola on Nov 29. The speakers: Dr A C Martin, Dr O C Hudson, Dr Richard Derby, and Dr A S Warinner.

New York County

At the 133rd Annual Meeting of the Medical Society of the County of New York on Nov 28, Dr Walter P Anderton was chosen president-elect. His term will start Jan 1, 1940. He will succeed Dr Howard Fox, whose term begins Jan 1, 1939.

Alfred M Hellman was named first vice-president, Maximilian A Ramirez second vice-president, B Wallace Hamilton secretary, Joseph A Devlin assistant secretary, Kirby Dwight treasurer, Edward C Brenner assistant treasurer, and Albert H Aldridge, George Baehr, and J Stanley Kenney censors.

Samuel B Burk was elected chairman of the committee on legislation, Harold B Davidson, chairman of the committee

on civic policy, Roy B Henline, chairman of the committee on economics, and Francis N Kimball, chairman of the committee on membership

Dr Bandler was named a trustee and the following were named delegates to the Medical Society of the State of New York: Samuel B Burk, Alfred A Cinelli, B Wallace Hamilton, Alfred M Hellman, David J Kahski, J Stanley Kenney, Francis N Kimball, Samuel J Kopetzky, James Alexander Miller, Peter M Murray, and Edward K. Barsky

Dr Malcolm Goodridge, Professor of Clinical Medicine at the Cornell University Medical School, was elected President of the New York Academy of Medicine for two years beginning on Jan 1, at the annual election of officers at the Academy's headquarters on Dec 1

Dr Rufus I Cole, former director of the hospital of the Rockefeller Institute and past president of the American Association of Physicians, was elected vice-president of the academy for three years

Dr Bernard Sachs, past president of the academy, was elected treasurer for three years. Dr James Alexander Miller, retiring president, and Dr Charles F Tenney were elected trustees for five years. Dr Carl G Burdick was elected trustee to fill the unexpired term of the late Dr Frederick Tilney, running through December, 1940

Dr S. S. Bauch was elected president of the New York Physicians Art Club at the annual dinner of the organization on Nov 28 at the National Arts Club. Other officers elected were Dr Alfred Braun, vice president, Dr J. R. Gudger, secretary, and Dr I. Rosen, treasurer. Dr Percy Fridenberg was reappointed publicity secretary

Dr Walter C. Alvarez of the University of Minnesota School of Medicine, will speak at the New York Academy of Medicine on Jan 12, at 8.15 o'clock, on "Emergence of Modern Medicine from Ancient Folkways," one of the series of "Lectures to the Lasty"

Drs Rudolf Schindler and Burnill B Crohn will speak at the New York Academy of Medicine on Jan. 5 on the diag-

nosis and medical treatment of peptic ulcer

Dr Arthur M. Master will give two addresses on Electrocardiography in Room 20, New York Academy of Medicine, at 3 30 o'clock on Jan 10 and 24

Onondaga County

The Maternal Welfare Committee of the Onondaga County Medical Society held a one-day Institute on Obstetrics on Dec 8, with a distinguished list of speakers. The committee paints a somber picture of the county situation, with the maternal death rate over 50 per cent above the figure for the state, and urges the physicians to "honestly assume our real responsibility and lead Onondaga County out of the dark situation in which we find ourselves"

Putnam County

In place of the regular monthly meeting, the Putnam County Medical Society held a fellowship dinner at the Carmel Country Club on Nov 9, at which time the physicians were hosts to the twenty practicing lawyers of the County. Dr Ralph M. Hall of Cold Spring, President of the Society, presided and the speakers were Hon. Lee Parsons Davis, Justice of Supreme Court, 9th District, Dr Joseph S. Lawrence, Executive Officer, and Dr Theodore West, President of First District Branch

At the October meeting, at Carmel Country Club, the speaker was Dr Walter Timme and the subject, "Recent Advances in Endocrinology"—*Reported by John T. Jenkin, M.D., Sec*

Queens County

Dr Henry Eichacker of Ridgewood, president of the Queens County Medical Society, won a sweeping—though possibly temporary—victory in his long drawn-out battle with the New York Telephone Company, on Nov 17

The Appellate Division of the Supreme Court, ruling on an appeal made by the physician, unanimously reversed the verdict by which Dr. Eichacker last year lost his suit to recover \$209 from the company

The amount represented, he contended, the difference between office and home rates charged by the company. His counsel argued that the company had no right to charge the higher office rates for use of a residence phone.

Dr Eichacker's office is in his home.

The telephone company, faced with the prospect of a barrage of similar suits should the physician's case be upheld, battled the issue vigorously until decision was rendered in its favor in June, 1937.

Justice Harold J. Crawford in Ridge-wood Municipal Court held that the company had a right to charge business rates for a telephone used for such purposes, although installed in a residence. The Appellate reversal, in part, reads:

"Plaintiff made out a prima facie case. The undisputed testimony shows that the plaintiff conducted his medical business in his residence. Under such circumstances he was entitled to the benefit of the tariff filed with the Public Service Commission."

The telephone company must now pay the \$209 judgment plus \$30 costs, or take the case to the Court of Appeals.

The Kew-Forest Medical Association, composed of surgeons and physicians in Forest Hills, Kew Gardens, and Richmond Hill, held an organization meeting on Nov. 21 in the Forest Hills Inn.

Plans for a new hospital in Forest Hills, which the association is working for, were discussed.

Rensselaer County

Dr. John F. Erdmann of New York City, was guest speaker at the annual banquet of the Rensselaer County Medical Society, at the Hendrick Hudson Hotel, in Troy, on Dec. 14.

Richmond County

Dr. A. C. De Graff will give two addresses on Electrocardiography at the Richmond Borough Health Center at St. George, S. I., at 4:30 o'clock on Jan. 9 and 16. Physicians and medical students are invited.

Rockland County

An interesting course of lectures on internal medicine was arranged by the Rockland County Medical Society in November and December, at the Summit Park Sanitarium at Pomona. The speakers were from the Long Island College of Medicine.

Suffolk County

At the one hundred and thirty-third annual meeting of the Suffolk County Medical Society on Oct. 26 at the Crescent Athletic Club, Huntington, Dr. Willets W. Gardner of Patchogue was elected president. Doctor Gardner will take office at the January meeting, succeeding Dr. Earl McCoy of Central Islip.

Other officers elected were Dr. J. L. Sengstack of Huntington, first vice-president, Dr. George P. Bergman of Mattituck, second vice-president, Dr. Edwin P. Kolb of Holtsville, secretary, and Dr. Grover A. Silliman of Sayville, treasurer. The censors elected were Dr. Paul Nugent of East Hampton, chairman, Dr. Warren Eller of Sayville, Dr. Frank McGilvery of Smithtown, Dr. Leon Barber of Patchogue, and Dr. Victor K. Young of Riverhead.

Westchester County

The need of a national program for medical care under the leadership of the A. M. A. was stressed by several speakers at the annual meeting of the Westchester County Medical Society at White Plains on Nov. 15. Dr. Ralph T. B. Todd, of Tarrytown, was elected president, Dr. Henry J. Vier, White Plains, first vice-president, Dr. Reginald A. Higgins, Port Chester, second vice-president, Dr. Robert B. Archibald, Bedford Hills, secretary, and Dr. James G. Morrissey, Yonkers, treasurer.

Drs. Restin, Romeo Roberto, Yonkers, and Robert W. Helm, Ossining, were elected to the Board of Censors, and Drs. Arthur F. Heyl and George C. Adie, New Rochelle, and Edward C. Wood, White Plains, delegates to the State Society.

Hospital News

An Obstetrical "Flying Squad"

THE emergency service, or so-called "flying squad," is now 'an essential part of a modern maternity service," said E Farquhar Murray, M D, F R C.S., Professor of Midwifery and Gynecology, University of Durham College of Medicine, in a paper read in the Section of Obstetrics and Gynecology at the Annual Meeting of the British Medical Association, Plymouth, and now published in the *British Medical Journal*.

The emergency service, which is everywhere adopted in the Newcastle area, is a something by itself. The essential points are that expert attention is immediately forthcoming, while the outfit, which is accompanied by a nurse, contains all reasonable surgical requirements and also those things which are often lacking in an industrial household, such as blankets, hot water bottles, basins, and so on. It is especially designed to deal with those acute crises which may occur in the most carefully supervised case but are more liable to happen in the present somewhat disjointed system of maternity service. Shock and postpartum or antepartum hemorrhage are typical examples of the cases most urgently in need of such a service, but threatened or actual eclampsia and difficult labors or "failed forceps" cases would derive benefit also.

How the Service Works

It is obvious that expert service given on the spot to a patient who is shocked and collapsed from postpartum hemorrhage and with a retained placenta is preferable to the delay and handling of a desperately ill woman entailed by sending her in an ambulance to hospital. For local calls the service can be in the patient's house as soon as an ambulance would be likely to arrive, and for distant calls long before the patient could have reached a hospital.

A doctor faced with an emergency sends a message to the maternity hospital giving his name, the name and address of the patient, and the name of the consultant on the panel he wishes to attend. He may also give some details of the nature of the case. This message is sent by private telephone or by a telephone kiosk, or by one of the police-box telephones. On receipt of the message the hospital telephones for a taxi and details a nurse to go with the outfit, which is kept packed and ready. The consultant is telephoned, and if he is not in then the others on the panel are approached. When one is obtained he goes to the patient's house, taking his usual outfit.

There is a friendly rivalry as to whether the nurse or the consultant will reach the patient first. On arrival at the case the nurse discharges the taxi, which can be sent for when necessary. For cases over five miles from Newcastle the consultant calls at the maternity hospital and takes the nurse and outfit with him in order to save needless transport charges. The nurse detailed is usually one of the district staff nurses, but a more junior nurse is occasionally sent. It is most important that the outfit should be clearly labeled with details of the contents of each package so that a nurse unacquainted with its contents can find them readily. The Newcastle outfit consists of a large tin, a large package, a drum, and some oddments such as a cylinder of oxygen and a container of gum saline. It can easily be carried in the boot of a motor car.

The panel of four is composed of those engaged in private consulting practice in the city. For consultations other than emergency, doctors make their own arrangements direct with the consultant.

The outfit, with a nurse in attendance, has been placed at the disposal of the Newcastle doctors, since it contains many things that might be most useful

in a difficult case and yet not one that requires the presence of an expert. Those doctors using it have to be responsible for the fee for the use of the outfit and for transport charges.

A Steadily Growing Demand

The service started in October, 1935, and there was only one call that year. In 1936 there were eleven calls, and in 1937 twenty-one calls. There were thirteen calls in the first half of 1938. A steadily increasing demand is made on the service, but not nearly as large as it should be. Badly shocked, exsanguinated, and sometimes moribund women are still sent to hospital from time to time. In 1936 eleven women were admitted suffering from shock and loss of blood, mostly due to placenta praevia, and died within a few hours of admission. It is impossible to believe that some of these deaths could not have been avoided had the emergency service been called in.

Certain of these disappointments are explained by failure of the authorities to give the service sufficient publicity. The profession is a constantly changing one, and annual reminders should be sent out. There is also the instinctive tendency to ignore literature received in open envelopes with half-penny stamps. Other disappointments are due to the deep-rooted belief in hospitals and the marvels that they can accomplish held by the relatives, who no doubt bring pressure to bear. They are unaware that the residential staff may only be a very junior house-surgeon.

Another factor is a dread on the part of certain doctors that the patient will be required to pay a part or the whole of the charges incurred by calling in what is believed to be a free service. Whatever the explanation, my colleagues and I are convinced that we have saved a number of lives—and in just such cases as those which simply cannot be saved when first seen at the maternity hospital.

Expenses and Fees

As for expenses, there is a charge of one guinea, or about \$5, for the use of the outfit with the nurse in attendance. The fees payable to the consultant are based on arrangements with local authorities. The Northumberland County Council pays these fees.

A primary consulting fee of two guineas, or about \$10, with a mileage rate for every mile traveled, going and coming, of 2s6d (about sixty cents) or 3s (about seventy-five cents) at night. Operative fees are additional, and range from 6 guineas (\$30) for an abdominal operation to 2 guineas (\$10) for a transfusion. Forceps deliveries, repairs, versions, and removal of placentae are intermediate in cost.

The operation of the service is simplicity itself, but for efficiency there must be a central call office responsible for receiving the messages. The panel should consist of all the recognized consultants in the work in any area who care to serve. In more outlying areas the panel could comprise practitioners conversant with obstetrics who commend themselves to their local colleagues.

What the Outfit Contains

The details of the outfit can be elaborated or amended according to the wishes of those who use it. A modified outfit should be at the disposal of every doctor and midwife, to make good the deficiencies of many industrial homes. Some emergencies are preventable, and will tend to be eliminated by the improved standard of medical and nursing supervision which is being developed and by the closer co-operation which will result between the two services.

This outfit is contained in (1) a bundle, (2) a square case, (3) a drum, and (4) oddments, with contents as follows:

Bundle (weight 21 lb., measurements 20 × 10 × 10 in.)

| | |
|-----------------------------------|------------------------------|
| 2 brown blankets | Bed-pan |
| 2 sheets | Rectal saline apparatus |
| 4 hot-water bottles | Tin containing 1 oz. glucose |
| 2 mackintoshes (1 sheet, 1 apron) | |

Square case (weight 27 lb measurements 20 X 10 X 10 in.)

| | |
|--|--|
| 2 pint measure | Sims's speculum |
| 1 small and 2 large basins | Catgut |
| Obstetric straps | Silkworm-gut |
| Flask of sterile water | Rubber catheter |
| Saline tablets | Detrol |
| Lotion thermometer | Pituitary |
| 2 sterile dressing towels and mackintosh | Erbolin |
| 1 hand towel | Morphine, digitalis, strychnine, lobellina |
| 1 pair of sterile gloves | Atropine |
| 1 bag of sterile swabs | Brandy |
| 2 pairs dissecting forceps | Adrenaline |
| 2 pairs artery forceps | Camphor in oil |
| 3 scalpels | Tinct iodine |
| Needles | Spirit soap |
| Aneurysm needle | Anesthetic mask |

| | |
|--|--------------------------------------|
| Scissors | Methylated spirit |
| Kidney dish | Coramine |
| Nail brush | Minim measure |
| Intravenous saline apparatus | 2 oz measure |
| Intra-uterine douche apparatus | Novocain |
| with Roze-man's nozzle | Chloroform |
| Hypodermic syringe | Ether |
| 10 cc. Record syringe | Drop corks |
| Dryas (weight 12 lb height 10 1/2 in) | circumference 32 1/2 in |
| Wool | 2 sterile gowns |
| Gauze (2 rolls) | 2 sterile masks |
| Lint | Doctor's hand towel |
| Gloves (2 pairs) | 4 dressing towels |
| Oddments | Flask of gum saline |
| Oxygen cylinder with tubing and funnel | CO ₂ apparatus for babies |

Newsy Notes

The income from patients' fees at the Lutheran Hospital of Manhattan, 144th Street and Convent Avenue, in 1937 was the highest in the history of the institution, Charles O. Pauly, managing director, reported in his annual statement to the board of directors. The number of patients, he said, rose from 2,982 in 1936 to 3,563 in 1937. The gross income from fees increased from \$109,561.63 to \$258,933.00. The highest previous annual income was \$244,983 in 1926.

The plan to have the Department of Agriculture divert surplus farm products to voluntary hospitals has received the support of Bert W. Caldwell, executive secretary of the American Hospital Association.

Dr. Caldwell states the voluntary hospitals of the country are caring for an average of more than 20 per cent charity patients and that another 40 per cent of their patients pay less than the cost of their care. Stating many of the hospitals are finding it difficult to carry this burden, he pointed out the diversion of surplus products to the hospitals would be a great help in the care of indigent patients.

Trinity Hospital, Brooklyn, will be forced out by the creation of a new public square that will include its site. Other sites are being considered for its new location.

Following the presentation of a paper on the "Preserving of Placental Blood

for Transfusions," given by Drs. Charles A. Gwynn and John B. Alsever at a meeting on October 7, 1938, the Syracuse Memorial Hospital Staff decided to establish a Blood Bank for use in emergency transfusions.

Loomis Sanatorium, in Sullivan County, forced into a suspension by a financial crisis, has received aid from the Bernarr Macfadden Foundation, and will probably reopen in May.

The Junior Auxiliary have made more than 20,000 pads, bandages, etc., for the Peekskill Hospital during the past year, and have donated a respirator, food-warmers, sterilizers, stretcher, and other appliances costing over \$1,200.

The formation of a hospital council of Greater New York to co-ordinate hospital services is announced by David H. McAlpin Pyle, vice-chairman of the Hospital Survey for New York. Seventeen organizations have become members of the council, which has headquarters at 370 Lexington Avenue.

The first undertaking, it is stated, will be to consider plans for the expansion or curtailment of services by mergers, rebuilding or abolition of obsolete plants and to check the proposals on an actuarial basis for financial solvency in operation.

Improvements

New York City's new \$8,000,000 Welfare Hospital for Chronic Diseases, on Welfare Island, will be equipped and ready for emergency service about April 1, although the official opening date is set for next July 1, it is announced by Dr S S Goldwater, Commissioner of the Department of Hospitals

Construction contracts aggregating \$2,099,115 for the new administration building at Bellevue Hospital have been approved by the PWA, Mayor La Guardia announces. Awarding of the contracts will set under way the last principal unit in the long-range program of development at the hospital

Pressure on the facilities of Kings County Hospital, which receives many patients from Queens, will be relieved by the erection of four new buildings adjoining present facilities

The City Planning Commission has included in its budget for 1939 completion of a new building for chronic patients at a cost of \$2,735,500. Another institution for patients with emotional or mental disturbances is proposed at \$1,430,000. To relieve overcrowding of clinics, an expenditure of \$1,087,500 is proposed. A central hospital laboratory, with facilities for the Medical Examiner's office of the county, is planned at a cost of \$400,000

The Veterans Administration in Washington has approved three contracts totaling more than \$2,000,000 for work on an addition to the U S Veterans Base Hospital 81, Sedgwick and University Aves, New York City

Plans for a \$500,000 hospital in Forest Hills, with 145 to 150 beds and all modern scientific equipment, have been announced by Dr Albert E Man of Forest

Hills, president of the newly organized Kew-Forest Medical Association

Tentative plans for a five-story building already have been drawn up, Dr Man said, and a site is expected to be chosen soon

The Schenectady City Council is seeking a PWA grant for the construction of a new wing at the city hospital

Ossining Hospital is making a drive for \$30,000 to cover the cost of a new x-ray department and other expenses

Dr F Dickson Brown is building a new, modern hospital at Hobart, Delaware County, to accommodate six adult and two child patients

Additions, alterations, repairs, and landscaping, costing over a half million dollars, will be made by the Works Progress Administration at the Neponsit Beach Hospital for Crippled and Tubercular Children

Additions to the hospital of the Home of the Daughters of Jacob, in the Bronx, New York City, have increased the beds by 86 to a total of 255

At the Helm

These hospital officials have been chosen

Dr William J Ryan, of the Summit Park Sanitarium, to be president of the New York State Association of Superintendents and Managers of Tuberculosis Sanitariums

Sister M Angela, to be superintendent of St. Francis Hospital at Poughkeepsie

Henry K Leworthy, to be president of the directors of Brooks Memorial Hospital at Dunkirk, re-elected

Harold G Metcalf to be president, and Lawrence E Kresge to be superintendent, of Auburn City Hospital

Dr Robert B Manning, to be president of the medical board of Peckskill Hospital, re-elected

Mrs Alfred E Frieman, to be general chairman of the auxiliaries of Southside Hospital, at Bay Shore

Lincoln Cromwell, to be president of St Luke's Hospital, New York City

Dr Joseph D'Errico, to be president of the medical staff of the De Graff Memorial Hospital at Tonawanda

Dr Joseph Baum, to be president of the medical board of St. Joseph's Hospital, at Far Rockaway

Miss Beatrice Spargo, superintendent of the Samaritan Hospital at Troy

OUR GREAT MEDICAL MOVIE THRILLER

It's like a movie the great national medical drama that is marching across our stage with its heroes villain, and everything. The audience is the public," remarked Dr Peter Irving the other day in an address in Syracuse at a Conference of Social Agencies. He went on

Legislators sit in the mezzanine. Many of the doctors have aisle seats so they can leave quickly in case of fire. Scenes in the picture which show an improved public health service are pleasing to the doctor. He applauds as he views more satisfactory handling of the health of the indigent insurance for workmen's compensation voluntary insurance for hospitalization and for budgeting the doctor's bill. But he has only hisses for the villain in the piece, compulsory health insurance. As he looks upon the screen he hopes that the play will come out well for the audience, who are paying their money to see it, so that he and his patients can enjoy the full benefit of each other's confidence, thus enabling him to give all that he can give—"his very best."

We must not suppose that the doctor is against all socialization in medicine. Dr Irving keenly pointed out in another address before the Rotary

Club of New York City. In many ways, he remarked, medicine is now and for a long time has been socialized. Sometimes I think people lose sight of that fact. The term socialization I am using to imply the use of community property in this case tax funds, to pay doctors

All public health service rendered by departments of health is an example of socialization in medicine and it has had thorough acceptance by the private practitioner over the course of years. What is more, he considers it a very bright spot. Particularly in New York State he is enthusiastic over its accomplishments. I would point to the drop in mortality rate from tuberculosis and the advances in treatment of pneumonia as typical instances. The practitioner has said as recently as Sept 17 1938 through the formal action of the American Medical Association that he would like to see this service extended in several ways.

But should the State endeavor to extend its medical activities to accompany the doctor across the threshold of the sick room, and place the hand of government upon the patient's pulse then would the organized practitioners say as at Verdun "They shall not pass."

MUTUAL MEDICAL PLAN FOR DISTRICT OF COLUMBIA

A proposal to provide a mutual health service for low income groups on a small monthly payment basis has been submitted by the Medical Society of the District of Columbia to its members for approval or rejection.

As the basic features of the program were adopted by the Society in October it is predicted the detailed plan will likewise be accepted.

Indicated to be an outcome of repeated charges that the private medical profession is not properly serving the low-income groups the new plan is advanced as an experiment to be tried for a year if 5,000 persons subscribe to the service.

To be eligible for the service subscribers must have incomes of \$2,000 or less a year if single and of \$2,500 or less for husband and wife, with

\$200 additional for each dependent. They must also be employed persons under 60 years old and in sound body and mind and with no known pending medical need.

Subscribers' dues are \$1.50 a month for a single person, \$2.50 for husband and wife, and \$3.50 a month for a family.

A subscriber may have his choice of a physician among participating members of the Society and a physician may decline such selection.

The doctors, subject to the Society's ethical code, must conform with the rules of the Mutual Health Service accept a fee schedule now being prepared, and agree to deduction of 20 to 40 per cent of their fees during the experimental period to maintain a cash reserve for the service.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

"Cancer Cure"—Responsibility of Physician and Hospital

A VERY unusual case recently came before the Court of Appeals of this state in which the question arose of the responsibility of both a physician and a private hospital in connection with the use of a so-called cure for cancer *

The facts in the case were quite extraordinary, and to appreciate the effect of the decision of the court it is necessary to relate in some detail the story of the case as it was developed by the evidence upon the trial

The plaintiff in the case, one H, was a truck driver who had suffered for some time from a sore on his lower lip. He had received various forms of treatment for it but it continued to trouble him. He heard of the defendant D, a chauffeur who had sold certain remedies to cure skin ailments. It seems that D had recently been in Ireland where he had obtained a remedy for the cure of cancer which was said to have been there used in his family for over two hundred years. D met with H and made representations concerning cures by the use of the remedy, which was in the form of a salve. He displayed Irish newspapers containing accounts of such cures, and told him that the ailment could be cured by the salve in thirty-one days. H apparently remained somewhat skeptical, and further meetings were had with D. H's brother was brought into the matter for the purpose of financing the treatment, and it was decided upon his suggestion that a doctor should first approve and supervise the treatment.

Finally, D told H that he had secured a doctor, and took H to the office of Dr. E, a practicing physician. E made a superficial examination of H, and expressed the opinion that the case was a very serious one, the cure for which

would cost \$10,000. The fee was later reduced to \$3,000. After arrangements were made with D and the doctor, H was taken to the P Hospital by D. Upon arrival, they met Dr. E who introduced D to the superintendent and executive manager of the hospital as "the man who has the cure."

H was placed in bed and D, in the presence of Dr. E, proceeded to grind a compound of arsenic and make a paste. Dr. E indicated the place on the patient's chin where the paste should be applied by a plaster, but he was told by D, "No, I don't want it that way. I want it my way." Dr. E then answered, "All right, go ahead," and left the room. He did not return to see H for over two weeks.

D proceeded to apply the paste, in the presence of a hospital nurse to whom he explained that he was not a doctor. He further told her that the paste contained "the most powerful poison in the world" but that it was controlled by his herbs. D's name and telephone number were written on the hospital record as the person to notify in the event of complaints of pain. Subsequent developments were referred to in the opinion of the Court of Appeals as follows:

"In two or three days appellant commenced to suffer pain and his face commenced to swell. D put new skin on the lip where the abrasion was, in an effort to stop the flow of saliva. He told the nurses to administer aspirin and whisky in case of pain, and they did so. D was present most of the time, 'in and out all day long.' He told the nurse how to put the bandage back on if it fell off. Every day D brought as many as eight or ten people into the room, took off the bandage and demonstrated his treatment, gave a talk on his cure, exhibited pictures

* 276 N. Y. 252

of S (a previous patient of his), and clip pings from the papers in the presence of the nurse. After appellant had been in the hospital two or three weeks, Dr E came into his room with Mr G (the superintendent) and a hospital doctor. He said, 'I will show you this and see how he is progressing.' He took the outer bandage off and pulled down a part of the bandage with the paste on. He said, 'I don't know a darn thing about this this is all new to me.' The hospital physician asked him, 'Didn't you have that analyzed or looked into?' He replied, 'No. It is his secret. The only one that knows anything about it is him (D).' He said he could not have it analyzed because there are herbs in it and you could not find out what the herbs are. 'The herbs nobody can find out. He is the only one that can get it. Mr G, the superintendent said 'We will have to play along with him (D). If everything comes out all right, we will all be taken care of.' One night appellant suffered a hemorrhage and the nurse telephoned D. On one occasion when appellant had a hemorrhage, a house physician was called in to stop it. The paste was allowed to remain on appellant's face for twenty-one days, although medical experts testified that it should never be allowed to remain on over eighteen hours. Appellant remained in the hospital fifty nine days, at the end of which period his hospital bill was in arrears, and G, the superintendent, insisted upon his leaving. When appellant left the hospital the flesh had been eaten away from the lip and chin. There was no lip or chin left, and his teeth fell out. It is not necessary to give the horrible details of his condition.

H instituted an action against D, Dr E, and the P Hospital to recover damages for the injuries that he had sustained. Upon the trial there was expert medical testimony to the effect that the injuries were caused by the administration of the salve. The jury rendered a substantial verdict in favor of the plaintiff against all of the defendants.

Of all of the defendants the hospital

alone appealed from the judgment. When the case came before the Appellate Division, that Court divided three to two ordered a reversal as to the hospital. A dissenting opinion was handed down in which the following was said:

'Defendant D, who had no license to practice medicine, was a fraud and a quack. His alleged cancer cure had no merit whatsoever. On the contrary, it was dangerous to human life. The results show that. Defendant E knew nothing about the cure. He made no investigation of it. The facts fully justify the inference that his sole interest was the receipt of the \$3,000.00 fee, that he was as indifferent to results as he was to method, and that he permitted his position in the hospital to be used as a cloak, cover, or pretense for the treatment of the patient by D, who applied the treatments during his almost every day visits to the hospital. The nurses of defendant hospital knew the treatment was in the hands of defendant D, and not of defendant E. They accepted orders from defendant D. Nurses are not expected to advise the administration if they are of opinion that a doctor is not using proper methods, for they are under the supervision of the doctors. But here they observed that it was not a doctor who was treating the patient, although the doctor was engaged for that purpose. This was a concern of administration and not of medical care.'

The matter was taken to the Court of Appeals by the plaintiff, and he succeeded in finally obtaining a reversal of the order of the Appellate Division and a reinstatement of the judgment of the Trial Court against the hospital, as well as against the defendants Dr E and D. The Court of Appeals in so ruling said, in part, in the opinion:

"The evidence introduced by the appellant, if believed by the jury, as we must assume that it was, justified the jury in finding that the hospital admitted appellant knowing that the purpose of his being there was for an improper treatment by a layman, 'the man who has the cure,' as stated by Dr E when

he introduced D to Mr G, the superintendent, that the hospital records showed that D actually personally treated appellant, that nurses, hospital physicians and the superintendent and executive manager knew, during the period that appellant was in the hospital, that appellant was being treated by D, not under the supervision of a doctor, that the superintendent, G, knowing all about what was going on, stated, 'We will have to play along with him. If everything comes out all right, we will all be taken care of.' The superintendent knew that the paste being applied was a secret preparation, its contents known only to D.

"G, the superintendent, knew or should have known that D was engaged in the commission of a crime and that the hospital, in affording its facilities for pay, was aiding and abetting him in the performance of such criminal act.

"In the case at bar the basis of liability is not the negligence of the doctor or nurse in charge, but the wrongful conduct of the executive manager and superintendent acting within the scope of his authority in affording for pay the use of the hospital and its facilities for the purpose of the commission of acts which constitute a tort and a crime in violation of a duty owed a patient."

Broken Anesthesia Needle

A middle-aged man was referred to a general surgeon for possible surgery. The doctor found that he was suffering from a fissure in ano, a small fistula, and external and internal hemorrhoids. An operation was advised and the patient entered a hospital for the purpose. The surgeon concluded that the general condition of the patient indicated that the operation be done under a caudal anesthetic. Using a steel needle about three or four inches long, the surgeon located the sacral hiatus and introduced the needle through the skin and sacrococcygeal membrane into the sacral canal. One syringe full was injected and then in the course of discharging the second

syringe full, a slight swelling of the tissues in the lower sacral area was noted at a point above the introduction of the needle. The surgeon discontinued the injection and withdrew the needle and found that about an inch of the point was missing.

It was determined to make an immediate attempt superficially to try to find the broken fragment. Using novocaine, an incision was made over the sacrococcygeal junction at the midline, and deepened to about one-half inch. The search was unsuccessful, and after a half-hour of careful work the wound was closed. Thereupon, under a general anesthesia, the originally contemplated operation was uneventfully performed.

After the operation the patient was advised of the breaking of the needle, and after a week had elapsed and x-rays had been taken, the surgeon undertook the removal of the fragment under an anesthetic of gas oxygen. An incision was made beginning at about the base of the coccyx, extending upward in the midline over the dorsal surface of the sacrum. The incision was carried through the subcutaneous tissues down through the sacral hiatus, exposing the canal. The lower end of the canal was carefully examined and the needle was not found. Using a rongeur forceps, a portion of the roof of the sacral canal was removed. Not more than an inch in length of bone was removed, about one-fourth to one-half inch in width. The needle not being promptly found, an x-ray machine was brought to the operating room, and additional pictures taken with a probe lying in the canal. After the x-ray was taken showing the relation of the foreign body in position to the probe and to the parts, further search then located the foreign body in the canal, and it was removed. The wound was then closed.

Following the operation the recovery of the patient was complicated by inability to void normally. Frequent catheterizations were necessary for several weeks until the ability to pass urine normally returned. At that point the

patient left the hospital under the care of the family doctor. Convalescence although somewhat prolonged was satisfactory.

The patient brought a malpractice action against the surgeon, charging negligence in breaking the needle and also generally throughout the care rendered by the surgeon.

Upon the trial of the action before the court and a jury the issues primarily resolved themselves into where the needle was located after its breaking. Plaintiff's expert claimed that the x-rays showed that it was outside of the sacral canal

lying in the superficial tissues, and that the search made by the defendant was not justified.

On the contrary the defendant and numerous witnesses whose testimony obviously impressed the jury as being of a most trustworthy nature, stated that the needle was in fact in the position above mentioned, and that the defendant's procedure was in all respects proper and fully justified.

The jury rendered a verdict in favor of the defendant doctor, thereby completely exonerating him of all charges of negligence and malpractice.

ANNOUNCEMENT

Pneumonia Control Program

Post graduate Educational Institute in Pneumonia for the General Practitioner

Announcement is made of a post graduate educational Institute in Pneumonia for the general practitioner, to be sponsored by the Bureau of Pneumonia Control of the New York State Department of Health, the Medical Society of the State of New York, and the Medical Society of the County of Erie. The Institute will cover the subject of the Diagnosis and Treatment of Pneumonia, with special emphasis on serum therapy. The educational facilities of this Institute will be extended to the physician who is desirous of learning more in detail about the recent advances in the diagnosis and treatment of pneumonia and who is anxious to familiarize himself with the exact technique of serum therapy. The Institute will consist of

- 1 Talks by outstanding authorities on pneumonia, i.e., on the various aspects of the diagnosis and treatment of the disease with special reference to serum therapy
- 2 Small group demonstrations on blood donors of the actual technique used in the administration of

serum, the taking of blood cultures and the performance of sensitivity tests

- 3 Lectures and demonstrations on the use of oxygen
- 4 Informal discussions with the speakers and other authoritative physicians, regarding individual problems
- 5 Sound moving pictures, illustrative of the technical aspects of the serum treatment and the nursing care in the home, will also be shown

This Institute will be held in one of the hospitals in the City of Buffalo, shortly after January 1. No fee will be charged to those attending the Institute. Physicians in counties adjacent to Erie County are invited to apply for admission to the Institute. Applications, which will be accepted in the order in which they are received, should be sent to the Chairman of the Public Health Committee of the Medical Society of the County of Erie, Room 1810, Hotel Statler, Buffalo. Cards of admission will be issued after the final arrangements have been made.

Across the Desk

Why Europe's "Health Insurance" Does Not Insure Health

EVERY morning a street sweeper, with his little refuse cart, stops at the public drinking fountain just outside the Bank of England, in the heart of London, takes a cloth from that cart and polishes the cups. Then, with another cloth from the same cart, he wipes them out and stands them on the lip of the fountain. All clean for the day! In America the health officer would have the cups removed within 24 hours. In spotless Stockholm, too, you will see a public drinking fountain in the beautiful new railway station with six glasses in constant use.

These are but two vivid glimpses of health practices in lands with health insurance systems that we are being urged to imitate. They are recorded by J. G. Crownhart, Secretary of the State Medical Society of Wisconsin, who was sent to Europe by his Society last summer to study state medicine on the spot and report his findings. His report is now published, and may be put in a nutshell by saying that he finds the care of the sick under state medicine lags as far behind American practice as their common drinking cup is behind our sanitary drinking fountains. He finds, in fact, that health insurance in Europe, instead of insuring health, insures hasty and inadequate examination and diagnosis, scant attention, poor treatment, and routine medication. Nor is the drinking cup the only sign of backward health usage.

"Staff of Life" Open to Germs of Death

All over Europe, bread is marketed without wrapping and without even the ordinary precautions against contamination. Bread and rolls are carried in boxes on bicycles, open to the dust and insects of the street. Meats are sold on open counters with no refrigeration or protection from contamination, and are often exposed on shelves facing the street, free to the dust of every wind. Americans

going to Europe rightly take inoculation against smallpox, typhoid, and paratyphoid, but probably few of them realize the actually inferior health conditions in Europe that make it imperative. Our superiority in health matters is unknown to our own people, or they would never lend an ear to the agitation for foreign health insurance schemes that only insure poor health instead of good health. Europe would do much better to adopt American ideas and practices.

Secretary Crownhart was impressed again and again by the fact that Europe's medical and hospital standards are not those of America. This was indeed confessed by the director of one of the large public health institutes in Denmark. "Sickness insurance is a leveling device," he said. "It assures the mediocre physician just about the same rewards as he who would give an outstanding service if he were to have time. But the incentive is gone, and we develop fewer brilliant minds in our teaching centers and America captures the lead in health and in methods to regain it."

The Brick That Was Dropped

The Wisconsin Secretary sensed that he had "dropped a brick" when he modestly told various hospital authorities over there that he had "come to learn." He had figured this as a good introductory remark, but somehow it failed to strike the right key. He couldn't understand why, until finally a superintendent in the Midlands remarked:

"You said when you came to see this hospital that you had come to learn. Now what have you learned?"

"You have learned that in the expansion we are planning we will use plans from your American hospital magazines."

"You have learned that in hospital administration I was sent to your cities to learn of their advanced methods."

"You have learned that the medical

students prefer American textbooks for their clarity and fine illustrations.

"You have learned that the equipment that we are proud of is either American or modeled after it.

"You have learned that our hospital is old and without adequate building funds

"What, exactly, do you mean when you say you have come 'to learn?' "

This superintendent put the statement more baldly than others but not more so than the physician in Sweden who said, "Now that you had studied the operation of sickness insurance, tell me one thing—how is it that something so good in theory can be so bad in practice?"

What this physician meant by "bad in practice," says Mr. Crownhart, was not a failure to deliver a service of what we might term "relief medical attention," but its failure to deliver a service in any way comparable to that he personally had observed as general in practice in both the United States and Canada.

When Patient and Doctor Meet— What Then?

Many a dazzling scheme, as we too sadly know, often fades into futility in the inexorable test of actual practice, so what we really need to learn about state medicine is what happens when patient and doctor meet. Does the patient receive the right medical attention? If he does, then the scheme is a success—if not, it is a failure. All the rest is trimmings. Well, our Wisconsin secretary applied this test. He visited British panel physicians during their office hours, observed the patients, and gives us the picture. In ninety minutes in the evening the doctor usually must see from twenty to thirty people. It is clear, he says, that in such circumstances, "there can be no physical examination in the sense of the common and accepted practice in our own country," and in fact, "there was not, in the observation of the writer "

Part of the few minutes for each patient had to be given to making out the records required by the system, but these were so sketchy that "their worth from the viewpoint of clinical records approximates

zero " Even the report of the British Health Services admits that the panel doctor "often enough tends to become little more than an agent for signing certificates," and "for operating some thing more like a sickness licensing and registration system than a health service."

It was well summed up by a man at Manchester, obviously trying to do his best—obviously disturbed by his inability to make adequate examinations when he had a waiting room full of patients, and finally turning to the American observer and saying, "I know what you are thinking, but what would you? I do my best and simply must get on with it." That is why the panel practice is sometimes described as "a look and a bottle."

French Give the Pay to Patient

County societies contemplating "medical indemnity insurance plans" will be interested in the French scheme, patterned similarly to pay the doctor's fee. The French plan hands the cash to the patient and lets him pay his doctor, any doctor he selects. The patient is entitled to medical benefit for six months, and may have not only general practitioner service, but specialist treatment, obstetrical services, and dental care. Any qualified general practitioner or specialist may be called in, but the fee schedule is fixed by the rules. The fund pays 80 per cent of the physician's fee to the patient, who must pay the other 20 per cent himself, and must also pay any excess fee charged by the doctor above the schedule. This prevents unnecessary running to the doctor. In addition, the system has elaborate "controls" for visiting the patient, inspection, rediagnosis, etc., to prevent abuses.

Here we have, then, a plan that gives the patient free choice of physician and that tries to avoid the evils of other systems. It has been operating so few years, however, remarks the American investigator, "that it well may be that only future experience will provide a background on which sound conclusions may be drawn " Perhaps it is worth watching

The Sore Spot

Why Europe's "health insurance" plans are delivering Grade B, C, and sometimes Z, medical service was discovered by the Wisconsin secretary. Briefly, the insurance system is concerned chiefly in maintaining the integrity of its own fund against the tendency of the doctors and patients to run up expenses. The British doctor is accordingly given a handbook of standard medical prescriptions, and if he ventures to prescribe something not in the book that costs more, he may be called upon the carpet and, if not found warranted, made to pay for it out of his own pocket. In the official book of instructions to German doctors, too, is a sentence, "the thought of which permeates the entire German sickness insurance system," declares Mr. Crownhart. It reminds the doctor that "the cost of medicines in sickness insurance is mainly at the charge of a third party, the sickness fund," and cautions him that "this particular feature should always be kept in mind." Thus the manager of the system "becomes an agent to protect the financial integrity of the fund for the 98 per cent of the insured who are not ill at a given time against what he fears to be the otherwise uncontrolled inroads of the 2 per cent of the patients who are ill."

This blighting feature runs through practically all the sickness insurance systems of Europe, and Mr. Crownhart studied them all on the spot. He interviewed not only the administrators in the various countries, but spokesmen for labor, the farm, the hospital, the physician, and the patient. He found that

the sore spot is the irreconcilable conflict between the expense of proper medical service and the efforts of the managers to fight all payments down to the last penny. Every new medical and surgical advance saves life, but costs money, and the sickness insurance systems make no provision for anything of the sort. The urge to pinch every cent paralyzes all advance. The doctor who dares to use his own judgment does so at his peril. As one administrator flatly declared at an insurance conference in Vienna, "the risk is shifted from the insurance system to the doctor," and Mr. Crownhart adds that the doctor is loaded "beyond his capacity to render a sound quality of sickness care," and then "the system is insured—not the needs of the sick." In other words, the entire scheme is so planned that it defeats its own purpose, and the elaborate "health insurance" plans insure everything except health.

Take Mr. Punch's Advice

Has America anything to learn from Europe in health matters? We may well ask it as we survey this scene with the keen Wisconsin investigator, from the refuse collector rubbing the public drinking cup to the hurried and harried panel doctor giving "a look and a bottle."

Shall we imitate Europe's example?

The answer seems to be along the line of Mr. Punch's celebrated "advice to those about to marry."

"Don't!"

W S W

WHO TIED THEM?

New discoveries amaze us. The other day in a New York City court a quack, described as a "swanky chiropractor," hurriedly paid a \$100 fine after admitting that last September he wrote a prescription for one of the women detectives and charged her a big fee in his offices in the Madison Hotel, for diagnosing her pretended ailment as due to "knotted nerve ends."

A FEW MORE BILLIONS

It would cost the Government \$4,000,000,000 a year to establish a system of socialized medicine for the care of indigents, according to Dr. Charles G. Heyd, professor of clinical surgery, New York Postgraduate School of Columbia University, addressing the annual banquet of the Buffalo Academy of Medicine and the Erie County Medical Society in Hotel Statler, Buffalo.

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

REVIEWED

Clinical Endocrinology By Samuel A. Loewenberg M.D. Octavo of 825 pages, illustrated. Philadelphia, F. A. Davis Company 1937 Cloth

Although but little new is furnished by this volume its conciseness, orderliness, and completeness make it a welcome addition to the physician's library. Written by an internist for clinicians and students it becomes more comprehensive and approaches the subject with a much broader viewpoint than many of its predecessors. The various glands are viewed as units and as parts of a great system. A welcome inclusion is a fairly complete exposition of the mysterious pineal body

"Cognizance has been taken of the debatable questions as well as the known facts, and controversial problems are treated as such, care being taken to cite the outstanding opinions and their authors—the predominating opinions on questionable subjects are given at the end of each discussion." The clinical discussions are clear and well illustrated. A valuable addition is the chapter on the significance of laboratory findings.

The print is clear and readable. The reviewer recommends the book for both reading and ready reference.

CHARLES S. BYRON, M.D.

The New International Clinics. Original Contributions Clinics, and Evaluated Reviews of Current Advances in the Medical Arts Edited by George Morris Piersol, M D New Series One, Volume 1, March, 1938 Octavo of 322 pages, illustrated Philadelphia, J B Lippincott Company, 1938 Cloth, \$3 00

In this volume of the "Clinics," which is some 300 pages long, a remarkably comprehensive series of articles have been assembled. Each article seems to have been selected judiciously and with great care. The experimental work reported is sound and conclusive. There seems to be little, if any, excessive verbiage. If the following issues of this new series are of the same caliber, the publication will be one that every scientifically ambitious physician will wish to acquaint himself with very thoroughly.

GEORGE WEBB

Surgical Anatomy of the Head and Neck. By John F Barnhill, M D Quarto of 921 pages, illustrated Baltimore, William Wood & Company, 1937 Cloth, \$20 00

As a result of his many years as a clinician and a teacher of otolaryngologic anatomy, Dr Barnhill has produced a work of merit. It is an excellent guide for the otolaryngologist, dental surgeon, and ophthalmologist who may have the opportunity to work in the morgue or the anatomic laboratory. Its greatest value lies in the references to clinical symptomatology as related to the structures under consideration.

The value of the text is greatly enhanced by 431 illustrations, many of which are unsurpassed and most of which are original in their conception. The publishers as well as the author are to be congratulated on the make-up of the book. The fine paper and the large type used in its preparation are advantages.

MERVIN C MYERSON

Management of the Sick Infant and Child. By Langley Porter, M D and William E Carter, M D Fifth edition, revised Octavo of 874 pages, illustrated St Louis, The C V Mosby Company, 1938 Cloth, \$10 00

This is the fifth edition of an already well-received volume. A book dealing with pediatrics becomes almost obsolete every four or five years, so rapid have been the strides during the past fifteen years. The authors have realized this fact in presenting this revision. A vast amount of pediatric literature has been scrutinized in a painstaking manner. Heavy print and italics are well timed as aids for the busy practitioner.

The first part is devoted to handling of symptoms, such as pain, tenderness, fever, diarrhea, cough, etc. The second part is taken up with a more or less orthodox discussion of the various diseases by systems. The third part is given to methods, formulas, recipes, drugs, and poisons.

This volume is an excellent book on pediatric management.

THURMAN B GIVAN

Workbook in Elementary Diagnosis for Teaching Clinical History Recording and Physical Diagnosis By Logan Clendenen Quarto of 167 pages, illustrated St Louis, The C V Mosby Company, 1938 Cloth, \$1 50

With the appearance of this orderly, sound, and interesting volume, a handy, brief guidebook is offered students of physical diagnosis. There is no elaborate discussion of the physics of sound production nor any labored review of regional differential diagnosis, but rather a brief presentation of the essential of history taking and physical examination of the patient. Many fundamental signs are defined in the words of the original description. A number of helpful pen and ink drawings add to the value of the book.

NEW YORK STATE JOURNAL *of* MEDICINE

Editorial

The Indictment of the A.M.A.

As a loyal constituent body of the American Medical Association we would be less than human did we let the implication and the threat inherent in the finding of the District of Columbia grand jury pass into history without a word of comment.

The great daily newspapers have given the details, and also have voiced their opinions editorially. As far as the majority of them did express themselves, we are gratified in the evidence of their confidence in us. The issues are fairly met and however much we may deprecate the propaganda value of finding indictments to coerce acceptance of a method of medical practice, it is not our desire to enter into the details of this controversy at this time.

We may, however, emphasize our position. It is our deep concern that all schemes and plans shall be so devised that the quality of medical care shall not be sacrificed to the cheapness of the care, and the profession shall remain free of political supervision and control. The necessity of providing adequate and high quality medical care to the needy without resort to compulsory health insurance is our immediate problem, and we are on the road to its solution. We desire to work out our solutions gradually, nor does any stringent urgency exist in this state which needs compel haste and hurry.

We contend that we are not *'in trade,'* and our members who practice the art and science of medicine individually are not working *at a trade*. Were we for a moment to assume the contrary, then the corollary would confront us, and the practices and usages of trade unionism would be ready at hand for our use in striving for economic goals. Organized medicine has never contended that it was a trade union or a guild. Our primary concern is not our individual economic advantages, but that the people we are organized to serve shall receive a better quality and a higher grade of medical care.

A great record of achievement is ours: the lowest mortality and morbidity record anywhere, with hospitals and colleges maintaining standards which are the envy and the admiration of the world, a

record of co-operation with public-health agencies that is reflected in the fine health statistics of our people. We can afford to go to court and abide the issue. We have clean hands.

Medicine Looks Ahead

Events of the past two months furnish concrete proof that the face of medicine is turned toward the future. In at least two states and six large cities elsewhere prepayment plans are afoot to provide medical care for low-income groups.

In California and Utah state-wide programs will be launched by organized medicine within the next two or three months. New York City, Washington, D C, Kansas City, Buffalo, Detroit, and Milwaukee are formulating the details of plans soon to be announced. If these projects are successful they will speedily be adapted to the needs of other communities.

The method of local selection is far more practicable than nationwide compulsory insurance. In a country as large as this the available medical facilities differ from county to county, from state to state. Climatic variations, industrial conditions, divergences in income produce totally different medical requirements in different sections of the country.

Under the system favored by organized medicine, the profession in each locality would determine community needs and base its program thereon. Voluntary nonprofit prepayment plans would supply services which the low-income groups are unable to purchase on an individual basis. Government funds would provide for both domiciliary care of the indigent by the physicians of their choice and institutional treatment.

The broad and flexible program favored by the profession entails a minimum of bureaucracy and a maximum of actual medical care for each dollar spent. It retains the virtues of private medical practice at the same time that it makes the great resources of government available for individual health services.

In a Nutshell

In a defense of the course pursued by the District of Columbia Medical Society, Dr. Thomas E. Mattingly, a member of its Committee on Economics, summarizes the motives and policies of the organized medical profession in terms that any layman can understand. He lays no claim to perfection of method for the profession, but reminds the public "that our social objectives are just as al-

truistic though infinitely less speculative than those who seek our indictment "

The advocates of compulsory insurance try to make up for the weakness of their factual arguments by bitter attacks upon the motives of organized medicine Dr Mattingly reminds the public that the foes of the existing American system of practice have not a monopoly on altruism For thousands of years physicians have fought for the betterment of human health They cannot be accused of abandoning this fight merely because they refuse to subscribe to schemes which their experience and professional convictions reject

Contrary to a prevalent impression sedulously fostered by the proponents of compulsory insurance, medicine does not condemn all prepayment plans Dr Mattingly lays down four principles under which voluntary insurance is entirely acceptable to the profession

- 1 The patient must have the right to choose his own physicians
- 2 No tax subsidies should be granted to one class of citizens which are not available to every other citizen in the same circumstances
- 3 There should be free competition within the profession, and the physician's success should depend on merit rather than political favor
- 4 ' Under no plea of emergency should the patient be persuaded to delegate the control of medical practice to those *who promise more than reason and experience tell us they can deliver* "

As Dr Mattingly succinctly observes, "whatever the faults of the present system of medical care, it at least has the virtue of paying its way " The coming generation in this country will bear the burden of enough half baked reforms without adding to the load with compulsory health insurance

Those who oppose this scheme are not necessarily hard-hearted reactionaries or rogues, and the government should abandon the policy of treating them as such There are 'grave dangers terrifying potentialities,' in allowing 'any agency of government other than the lawmaker to legislate through subterfuge "

The state can effect many beneficial changes in the distribution of medical care by consultation and co-operation with the medical profession It will not effect any lasting medical good by starving or coercing physicians into acceptance of schemes in which they do not believe.

The Suprarenal Cortex

In the domain of research, the extirpation of organs remains one of the important means for the study of physiologic activity and endocrine therapy. As a by-product it has contributed immensely to the more exact evaluation of clinical signs and symptoms which in turn has led to the transplantation of the physiologic chemist from the laboratory to the bedside. Many clinical phenomena hitherto unexplainable are now known to be the result of a slight dysfunction of one of the glands of internal secretion.

The destruction of the suprarenal cortex has always been associated with the entity known as Addison's disease. It is only within recent years that extirpation studies of the suprarenal cortex have furnished us with a knowledge of the multiplicity of bodily functions which are dependent upon its normal activity. The metabolism of the mineral salts, particularly sodium and potassium, is profoundly affected by its removal, the viscosity of the blood is increased, and alterations are noted in carbohydrate, fat, and nitrogen metabolism. Clinically, early evidences of disturbed neuromuscular function are noted. Each and all of these phenomena can be corrected by supplying to the experimental animal an active extract of the cortical substance.

Confusion, however, still exists concerning the earliest sign or symptom of adrenal cortical dysfunction in humans. This is but natural since in the various animals used for research, some appear earlier in one species while different ones have been reported to become manifest sooner in others. From all the experimental data at hand, we may expect soon a clearer clinical concept of the effects of disturbed suprarenal function. Rhinologists, for example, have reported decided benefit in vasomotor rhinitis from the use of extracts of the suprarenal cortex administered together with dilute hydrochloric acid. Hislop¹ has found that the intramuscular injection of cortin gave good results in marasmus. All indications point, therefore, to a broadening of the scope of the use of suprarenal cortex as a therapeutic agent.

The Diabetic Situation

It is interesting to reflect upon the changes which have resulted in the diabetic situation since the introduction of insulin. With the marked increase in the diabetic population which has been brought about by the reduction in fatalities there have arisen problems in the prevention of diabetes and management of the mounting

¹ Hislop. *Lancet*, 2: 308 (1938).

number of diabetics Joslin¹ estimates this number as three times that which existed fifteen years ago Because the disease is of such nature that at the present time it can only be controlled rather than cured, the care of the patient should logically fall to the family doctor rather than to the specialist The dietary regime is simple of application and the rules for insulin medication are standardized The addition of protamine zinc insulin has further simplified treatment, so that with this armamentarium, the general practitioner is competent to guide a diabetic along a successful course

The attention of the metabolists is now being directed more toward the field of prevention Only recently has the significance of heredity been realized as an important factor in the development of this fundamental metabolic defect This follows the laws governing the transmission of recessive traits It is strongly urged that two known diabetics should not marry and have children, nor should a diabetic marry a person of diabetic heredity² The avoidance of obesity in a predisposed individual and a measured daily carbohydrate intake in an otherwise average normal diet are recommended as preventive measures Finally, recent experiments have proved that diabetes can be artificially produced by the injection of anterior pituitary hormone in animals without injury to the pancreas¹ This result, achieved by means of a hormone, leads to the belief that there exists within the body a counterprinciple that is capable of preventing one from having the disease

Until such time as the treatment of diabetes will be altered we are still confronted with the increased number of living diabetics whose best assurance for their continued well-being lies in the efficient, scientific control of their malady by their family doctors

A Service to the Rochester Community

Public minded and civically inclined laymen have just made a contribution to the whole Rochester community by dedicating to the Rochester Academy of Medicine a new auditorium, library, and museum The ceremonies took place from January 11 to 13, and were of intense interest to both the local profession and the public

The function of an Academy of Medicine in the co ordinated ranks of medicine carries out a different function than that performed by the units of organized medicine Largely its function is of educational import and dependent upon the success with which it carries out this function, it stands in a given community as a symbol of progress in medicine But in addition—because the teacher has

¹ Joslin E P N Eng. J Med. 219: 847 (Oct. 13), 1938

² Adlersberg D and Segal S N Eng. J Med. 219: 104 (Aug. 11) 1938

always held a place of high esteem and because his rôle is obviously unselfish, an Academy of Medicine has come to represent to the public the unselfish and unself-seeking side of the medical profession. It is a source of information on the past history of the romantic rise of medicine—from a priestly cult to a science and an art. It is a center of ready reference to answer perplexing problems that occur in so many elements of life, and as one contemplates its activities one realizes—when it has finally established itself—that the community could hardly get along without it.

The Medical Society of the State of New York congratulates the City of Rochester for having made possible to itself this educational service which we feel sure the Rochester Academy of Medicine will fulfill for it.

Current Comment

"Man is mortal, man is frail. It may be that some fine day we shall all work for the pure joy of effort, that we shall strive and struggle with only the prod of the desire for efficient achievement. But that day is not yet. If I have to have a sawbones look me over, give me one who has some slight interest in getting me back into the pink. Put ten doctors—or ten men of any profession—in one organization, pay them all approximately the same, make it difficult if not impossible for any one to get fired. In a month, two are doing all the work, while the others play golf. Quoting from "State Medicine, Navy Style," an article from an anonymous contributor, in the January *American Mercury*

. . .

"Most of the idealism, the self-sacrifice, the unselfishness, the burning passionate interest in the welfare of humans, the unflinching devotion to their duty, and the deepest religious convictions that exist in the young men who begin their lives in America, you will find in those young men who enter medical schools. We believe that Thurman Arnold has unwittingly raised an issue that lawyer-politicians would prefer to keep quiet.

How much more of our freedom of ac-

tion, of our liberties to engage in the exchange of goods and services, must we sacrifice to the obsessions of legalistic department dictators in Washington who have unlimited power to regulate a productive system which they do not understand?" From the editorial page of the *New York Daily Mirror* of December 22, 1938.

. . .

"If the case is fought through the courts, as the medical association promises that it will be, it must end either in a victory for them, which would leave everything as before, or a defeat which might very gravely jeopardize their invaluable function of generally policing the profession." "The Doctors Are Indicted," and the *Herald Tribune* of December 22, 1938, comments editorially thereon.

. . .

"We all know we are too self-willed and impatient and lazy to follow a doctor's directions. We all know that cooperation and obedience are the rarest virtues known to mankind. Until we Americans, rich and poor, agree to cooperate with our medical adviser and obey his decrees, discussion of bigger and

better medical attention is just so much piffle.

As a matter of fact, most of us think we know more about ourselves than the doctor possibly can. At least, if we do not think so, we give a letter perfect imitation of thinking so. To this fact is due a great deal of the enormous cost for medical attention in the United States which is the fundamental basis from which those who would socialize medicine bring their argument.

Frankly, the nation needs socialized medicine much less than common sense. If patients had more of that commodity, and realized the folly of seeing a physician and then stubbornly refusing to follow his instructions, there would be less serious illness and fewer premature departures from this vale of tears by persons who are really ill but knew entirely too much to follow their doctor's advice." A clipping from the San Bernardino (Calif.) *Telegram*

"There is this difference between the two temporal blessings—health and money, money is the most envied, but the least enjoyed, health is the most enjoyed, but the last envied, and this superiority of the latter is still more obvious when we reflect that the poorest man would not part with health for money, but that the richest would gladly part with all his money for health"—Colton

"As to how many people can be included in the 'medically indigent' group, there is, of course, no definite standard. It is a strange coincidence that on one hand we hear loud cries of inability to pay medical fees after meeting the 'necessities of life,' and on the other hand equally loud cries from Health Conferences that medical services are so great a necessity of life as to require a special social service plan 'Consistency, thou art a jewel.'" Recently published comment in the Columbus Academy of Medicine *Bulletin*

"The Medical Trades Assembly is busy these days with matters of jurisdiction. There is still the question of where gastro-

enterology leaves off and proctology begins, whether the application of hot stupes is physiotherapeutic or in the realm of the internist, whether paracentesis abdominalis is a medical or a surgical measure, whether eczema is dermatologic or allergic, etc., etc.

"This confusion is the result of the loose methods and unfair practices that existed before the entrance of medicine into craft unions.

"In those ancient days it was not an uncommon experience to find an obstetrician prescribing a feeding formula for a baby, an abdominal surgeon reducing a fracture, or an internist ordering a hot water bottle.

"In those benighted times there were even those who called themselves general practitioners and who transgressed with impunity the field of the obstetrician, the orthopedist, the pediatrician, and even the dermatologist. Since medicine has unionized, such doings are a thing of the past but the echoes of those days may still be heard.

Joe Bruznoski, business agent for Obstetric Local No. 24, calls attention to the new rule that goes into effect Nov. 2, whereby all obstetricians are required to have helpers. Fine ideal. More union members at work.

"We wish to call attention again to the rules as to working hours. No work may be done before 8 A.M. or after 5 P.M. and no work on Saturdays, Sundays, or holidays. Exceptions to this may be made only with the consent of the Committee of your Local. If a condition arises where you feel that something should be done outside regular working hours take it up with your Committee which meets every Thursday at 8 P.M. Under no circumstances are you to do anything until their approval has been secured.

"The question of jurisdiction in the present epidemic of scarlet fever has been referred to the International Union for Settlement." 'Union News from the Organized Medical and Surgical Crafts' heads the amusing satire to be found in the *Peoria Medical News* of recent date, from which we have quoted in part.

SURGERY IN HYPERTHYROIDISM

FRANK H LAHEY, M D , Boston

SINCE we have now performed 17,388 operations for goiters, of which 76 per cent have been for hyperthyroidism, it seems probable to me that the chairman of your program committee assigned the subject of surgery in hyperthyroidism to me with the idea that from this large experience certain practical convictions and deductions must have been drawn. In presenting this subject I am less interested in the technical side of the subject, although that is of real importance, than in deductions in this experience as relate to other aspects of surgery in hyperthyroidism, such as the diagnosis of borderline cases of hyperthyroidism, the avoidance of complications, the amount of thyroid tissue to remove, the control of mortality, and anesthesia in hyperthyroidism.

Any discussion of established and frank hyperthyroidism would be a complete waste of time since the diagnosis in these phases of toxic thyroid states is so self-evident. This is not the case, however, in many of the borderline states in which it is extremely perplexing to separate those nervous states of nonthyroid origin from those of thyroid origin. As yet there are available no measures by which this segregation can be quickly and certainly made. Determinations of basal metabolic rate, blood cholesterol, and blood iodine lend us little or no positive aid in separating these vague borderline states into those groups of thyroid origin in which surgery is justifiable and those of nonthyroid origin in which surgery is disastrous.

It is in this group of cases that ill advised surgery does much harm since not only is the gratifying improvement lacking which is so typical of subtotal thyroidectomy in hyperthyroidism but the already nervously shaken individual suffers greater intensification of this state.

As a result of this experience which we have had there is nothing which has been more strikingly impressed upon us than the fact that when a patient suspected of having hyperthyroidism is a borderline case there is not the slightest danger of him going into a thyroid crisis. There is not the slightest danger of this group of patients dying from delay. The history of practically every case of true hyperthyroidism is that with time it will reveal itself clinically as a definite hyperthyroidism, or in failing to do so will reveal itself as some other state. One can, I believe, state with reasonable assurance that a majority of the patients suspected of borderline hyperthyroidism will prove to be patients whose symptoms are of nonthyroid origin, and I would particularly stress what I have repeatedly stated, that is, when there is doubt of the diagnosis of hyperthyroidism that doubt should never be settled by operation but by delay and by permitting the individual by his clinical appearance to prove the presence or absence of hyperthyroidism. There will be few cases in our experience in which this proof will not eventually demonstrate itself one way or the other.

We have for a number of years privately stated that there are definitely patients with low-grade, chronic hyperthyroidism, possibly in temporary remissions who show normal basal metabolic readings. We have refrained from making this statement publicly because we believe it to be a most dangerous teaching and one which tends to lend itself to indiscriminate subtotal thyroidectomy. We have seen so many gratifying results following subtotal thyroidectomy in a number of these cases that it now seems worthwhile to call attention to the possibilities of this situation.

The diagnosis of hyperthyroidism and the submission of such patients to sub-

total thyroidectomy in the presence of a normal basal metabolic rate require a high degree of conscientious clinical acumen to properly select those cases in which the conditions are truly due to a hyperthyroidism often recurring in character, and to reject those cases in which symptoms are of nonthyroid origin. We feel that the outstanding clinical factor which must be present in this group of cases is, in the majority of instances, an enlargement of the thyroid gland, but in all cases, firmness of the thyroid gland when it is of the primary hyperthyroid type. Rarely will there be absent in the histories of such patients reports of long standing symptoms of hyperthyroidism with repeated periods of remission. The condition which will be most confusing in this situation which can be settled only

by those who have had a large experience in interpreting toxic thyroid states is that of thyroiditis associated with nonthyroid neurogenic states.

Because we have considered it likewise a dangerous teaching for general dissemination we have never before called attention to the fact that there are occasional patients with multiple colloid adenomas of the thyroid which have become semicystic or seminecrotic with normal metabolisms in whom, following the removal of these adenomas, general improvement appears similar to that following subtotal thyroidectomy in primary hyperthyroidism, with weight gain, pulse drop, restoration of pulse rhythm, and elimination of cardiac symptoms. We realize again in making this statement that it can be sadly misapplied and

lend support to the indiscriminate employment of subtotal thyroidectomy in patients with multiple adenomatous goiters which do not possess the least degree of toxicity. I believe nevertheless since it is my duty to make deductions from this large experience that I should frankly state that such experiences have led me to believe this to be a fact. Some of the most brilliant results which we have obtained by subtotal thyroidectomy, though relatively few in number, are in those older patients who have chronic, recurring, low-grade types of hyperthyroidism in which a very low or at times normal

Little need be said regarding the type of incision for thyroid operations. Concerning that there is almost universal agreement. The important point which we wish to make as a result of our experience with goiter scars in patients with prominent goiters is the compensatory placing of the scar at a higher level than it is desired to be, and the compensatory tilting of the skin incision when one side of the neck is more prominent than the other.

As is shown in the diagrammatic illustrations 1 and 2 of prominent thyroid glands, there will be considerable slipping of the skin following the subtotal thyroidectomy with the result that when the original incision is made at the desired level due to slippage this incision may well migrate down over the front of the chest, a most undesirable level where it cannot be concealed by any neck decoration. In those unilateral prominences of the thyroid, when a well balanced incision is made at the proper level following the skin slippage on one side the original symmetrically placed incision may be so tilted as the result of the unilateral slippage that a most awkward and undesirable scar will result. As is shown in the diagrammatic illustrations, in most patients having large prominent thyroids the skin incision should in a compensatory manner be placed at a higher level than it is desired to be following the removal of the thyroid, and, in those patients with unilateral enlargements of the thyroid, the portion of the incision over the enlarged lobe of the thyroid should be elevated compensatorily as compared with the opposite side so that following the removal of the thyroid tumor slippage will result in a symmetrical scar.

Tetany is undoubtedly one of the most distressing complications associated with the surgery of hyperthyroidism. It should, however, we believe, be largely a matter of the past. As evidence of this is the fact that out of this entire group of cases there have been but fifteen cases of permanent tetany and no permanent tetany has now occurred in this clinic.

III II

metabolic rate has been found. Likewise striking results, as already stated, have to our surprise occasionally followed subtotal thyroidectomy in patients with the necrotic or semicystic type of multiple colloid adenomatous goiter.

Since a majority of thyroid operations will be done upon the feminine sex it is but natural that considerable interest should relate itself to the scar. It is unfortunate that the gain in weight, drop in pulse rate, and loss of nervous symptoms in patients who have had subtotal thyroidectomy do not produce in patients the most lasting gratitude. Patients soon become adjusted to these improvements and forget that they were ever otherwise. A bad scar, however, makes an impression which is lasting and distressing.

in the past two years. These results have not been obtained by a single surgeon but by a group of surgeons operating upon these patients, and they are related in our opinion to the following factors: (1) adequate exposure which we believe can be obtained only by severing the prethyroid muscle, (2) a completely dry field, (3) an intense light obtainable only by special concentrated illumination of the posterior aspect of the thyroid, (4) a well developed anatomic knowledge of the color, shape, position, and possible relationship of the superior and inferior parathyroid glands. We are by no means certain that the autogenous transplantation of any parathyroids found upon the specimen, as we have suggested, into the sternomastoid muscle plays or has played a real part in the production of this low incidence of tetany. We do know that it has been proved that a patient's own parathyroid glands can be transplanted into his own tissue and there is no doubt in our minds that a parathyroid gland found on the removed specimen at the operating table is better off in a dry hole in the patient's sternomastoid muscle than it is in a pathologic laboratory.

When a successful accomplishment of tissue culture parathyroid grafts immunized to the host's serum was reported by Dr. Harvey B. Stone of Baltimore, we were thrilled by the possibility of cross grafting hitherto considered impossible. We have done tissue culture cross grafts in six cases with ultimate failure to maintain elevations of blood calcium in the entire group. Drs. Collier and Maddock, of Ann Arbor, have likewise reported unsuccessful end results in similar cases. The end results of the tissue culture parathyroid grafts originally reported by Drs. Stone, Bowing, and Guy have as yet not been reported. The delay in reporting end results in this group of cases, together with our end results and those of Drs. Collier and Maddock, makes it seem possible that the biologic law hitherto accepted that failure will follow cross grafting will in all probability be maintained. A. T. 10, which can be taken by mouth, developed by Holtz of

Berlin and now available in this country, has greatly simplified the management of parathyroid tetany when it has occurred.

It has always been of interest to me that certain procedures in surgery become traditional, are accepted without question, and are handed down unchanged from one generation to another. One of these has been the management of the recurrent laryngeal nerve in subtotal thyroidectomy for hyperthyroidism. It has been banded down from Kocher's time that the recurrent laryngeal nerve should not be seen and that sufficient thyroid tissue should be left over the recurrent laryngeal nerve so that there will be no danger of injuring it.

Three years ago I became convinced that this was not the best way of avoiding injury to this structure. I have repeatedly stated that it seems to me that the question of injury to the recurrent laryngeal nerve is similar to the question of injury to the ureter in hysterectomy. When the ureters were avoided by not demonstrating them but by placing clamps close on the side of the cervix many ureters were undoubtedly injured. When the method of dissecting and demonstrating ureters developed and when surgeons became expert in this procedure, injuries to the ureter became less in number.

Three years ago I instituted in our clinic the plan of exposing the recurrent laryngeal nerve in practically every operation upon the thyroid gland. I have purposely refrained from remarks on this subject up to lately until a sufficient length of time had passed and until a sufficient number of cases had been done so that a positive statement based upon a large number of cases over a long enough period of time could be made.

The reported incidence of recurrent laryngeal nerve injuries in the literature from several clinics has been around 3 per cent. Our incidence of recurrent laryngeal nerve injury up to three years ago was 1.6 per cent. In the past three years well over 3,000 recurrent laryngeal nerves have been exposed and the per-

centage of recurrent laryngeal nerve injury in that period has dropped to 0.3 per cent. We believe as a result of this good-sized experience with exposure of the recurrent laryngeal nerve one may safely say that exposure of the nerve in itself, provided it is handled with reasonable gentleness, will not result in injury to that structure. The course of the recurrent laryngeal nerve is extremely constant. It not infrequently runs over the inferior thyroid artery rather than under it and may easily be pinched in clamping bleeding vessels at the lower pole of the gland. It not infrequently runs beneath the thyroid tissue which overlies the part of the thyroid cartilage where the nerve becomes intralaryngeal so that the introduction of hemostats at this point to control bleeding vessels frequently causes it to be pinched at this level. It is to be recalled, as shown in the illustration, that the recurrent laryngeal nerve occasionally does not descend into the chest to recur but passes directly from the vagus nerve into the upper pole. Failure to dissect and demonstrate this abnormal position will result in its injury. As a result of this experience we feel that we may safely say that the recurrent laryngeal nerve should be demonstrated in all cases and that when it is demonstrated and its course outlined injury to it can be successfully avoided. If it has been injured it should be dissected and if severed its end united. We have easily found and sutured three such nerves cut elsewhere and sent to us for repair. The attitude that a cut recurrent laryngeal nerve cannot be found and sutured is a wrong one.

There is no place in surgery where anesthesia and anesthetists play a more important part than in the surgery of hyperthyroidism. In our experience in a large group of patients upon whom partial thyroidectomy has been done, we have been fortunate in having associated with us throughout the entire time a competent group of men whose entire time and interest have been devoted to anesthesia. We have passed through the employment of various agents to bring about anesthesia in thyroid operations,

beginning with ether. This was soon supplanted by local anesthesia, which in turn was supplanted by nitrous oxide, in turn being supplanted by ethylene which in turn has now been supplanted by cyclopropane. In the course of this experience we have arrived at certain quite definite deductions regarding anesthesia in thyroid operations. Of all the anesthetics, ether is the most undesirable anesthetic agent. Its induction is slow, it produces marked excitation, recovery from it is delayed and with it is associated not infrequently prolonged vomiting, a most undesirable complication in patients operated upon for hyperthyroidism. Vomiting limits the patient's attempt to maintain his metabolic balance and there is no single factor with which we are familiar which is better calculated to intensify toxic thyroid states than prolonged vomiting.

Local anesthesia we believe is undesirable because it makes the operation an emotional ordeal for patients to endure, because it disturbs the anatomy of the operating field, because it limits accuracy of exposure and anatomic dissection and finally because the mortality figures reported by those who employ it are no better than those using some form of inhalation anesthesia.

Nitrous oxide has the advantage of being almost foolproof from the point of view of depth of anesthesia, since when patients are carried too deeply with this anesthetic, jactitation occurs. It has the further advantage that it is not explosive. The disadvantages, however, in the surgery of hyperthyroidism more than outweigh its advantages. The particular objection to nitrous oxide as an anesthetic is that there is frequently associated with it in anesthetic mixtures but 10 per cent or less oxygen. A degree of anoxemia which can result in cerebral changes as sometimes occur with nitrous oxide anesthesia makes it certainly an undesirable anesthetic in patients with hyperthyroidism in whom there exists such high demands for oxygen (500 to 800 cc per minute as compared with 250 cc in the average individual).

Ethylene anesthesia, while a great improvement over nitrous oxide in the surgery of hyperthyroidism, is open to the same criticism as nitrous oxide in that in ethylene anesthetic mixtures there is present usually but 15 per cent or less of oxygen.

Cyclopropane possesses all of the desirable qualities lacking in these other anesthetic mixtures. It is as powerful an anesthetic agent as ethylene, it is not unduly expensive, and in anesthetic mixtures contains from 10 to 15 per cent cyclopropane, leaving a remaining volume of 85 to 90 per cent which may be replaced with oxygen. In actual practice, cyclopropane mixtures probably contain about 50 to 60 per cent oxygen. We have now employed cyclopropane almost exclusively in thyroid surgery since Nov., 1934, and have administered it in literally thousands of cases. In the beginning of our experience with it, it seemed an ideal anesthetic particularly for thyroid surgery. After wider experience with it, however, we are conscious of the fact that it too possesses certain defects from which the patient must be protected. It is particularly likely to bring about cardiac irregularities when patients are deeply anesthetized with it and when patients are carried into deep anesthesia under cyclopropane it must be realized that after the administration of the gas is discontinued the depth of anesthesia may still progress several minutes. Thus, precautions must be taken lest, particularly in cardiac cases, undesirable irregularities be brought about and precautions likewise must be taken lest dangerous depths of anesthesia be obtained. Our anesthetists have, in patients with hyperthyroidism and severe cardiac lesions, combined cyclopropane and nitrous oxide to lessen the coaction of cyclopropane in such cases.

The employment of helium mixed with oxygen as first proposed by Barach for asthma and applied by our anesthetists to anesthesia has been of great aid in managing the anesthesia of some of the patients with severe hyperthyroidism. Helium, a metabolically inert gas, when

mixed with oxygen has the property of so thinning oxygen that it will pass through a smaller aperture. In the mixtures of 80 per cent helium with 20 per cent oxygen it is possible to get in twice as much oxygen as can be introduced with oxygen undiluted with helium. In this large experience with subtotal thyroidectomy for hyperthyroidism we have often had forcibly impressed upon us the undesirability of prolonged laryngeal spasms and how disastrous are such interferences with breathing during the subtotal thyroidectomy when patients cannot receive adequate anesthetic and oxygen mixtures. It is in these cases that the employment of cyclopropane, oxygen, and helium mixtures has so frequently proved of great value.

Another point which we wish particularly to stress as relates to anesthesia is that if in the beginning of an operation for subtotal thyroidectomy there be difficulty with anesthesia, particularly as relates to breathing, an intratracheal catheter should immediately be passed. We have repeatedly had it demonstrated to us particularly in extremely toxic thyroids with marked thyroid vascularity that the combination of technical difficulties in the thyroidectomy with anesthesia difficulties, particularly as related to interference with breathing, can together bring about a fatality. It is infinitely better to take the time before the subtotal thyroidectomy is begun in these cases to introduce an intratracheal catheter, thus insuring a free airway, than to get into these airway complications in the midst of a difficult and bloody thyroidectomy. Still another point which we have always stressed and concerning which we still feel strongly is that anesthetists should observe each patient upon whom the anesthesia is to be given preoperatively and postoperatively in order that they may develop clinical judgment as to the degree of toxicity and as to the need of limiting the operative procedure, since once the operation is underway they are to be the ones to estimate the patient's condition.

Perhaps one of the most important

factors in the surgery of hyperthyroidism is the amount of thyroid tissue to remove. No specific statement can be made regarding this decision. It is here that one may safely state that in surgery as a whole it can always be said that there can be no substitute for experience. This is, however, particularly true in this situation. The experience gained from removing too much thyroid and from removing too little thyroid and the observation of such cases postoperatively is the only real way by which correct estimations can be made. There are, however, certain useful factors related to these decisions. The principal one is the individual's general reactions to iodine and the thyroid reaction to iodine. In those patients whose thyroid gland will involute well under iodine there will be drops in metabolism, gain in weight, drops in pulse rate, and improvement in nervous symptoms. When the thyroid gland of such a patient is under direct vision and an incision made in it, it will be found to be firm, pale in color, and of diminished vascularity. In those patients whose thyroid does not involute under iodine there will be little if any drop in metabolism, in fact, metabolism may rise, there will be no drop in pulse rate, no gain in weight, and no improvement in nervous symptoms and the thyroid gland of such patients will be soft, uninvoluted, red, and extremely vascular. In the involuted cases relatively large amounts of thyroid may be left with safety. In the uninvoluted cases, the latter group, radical removal must be done, otherwise persistent hyperthyroidism or recurrent hyperthyroidism will occur. In addition to the above, blood iodine studies which we have now conducted over the past four years, which will be reported upon at this Congress by Dr R B Cattell and Mr H J Perkin, have conclusively demonstrated an increased incidence of recurrent hyperthyroidism in those patients with long standing hyperthyroidism who, as the result of a negative iodine balance, have so exhausted their body iodine that instead of having the typical elevation of blood iodine, as is so frequently

associated with an elevated metabolism, show a low or normal blood iodine. When, as reported by Dr Cattell and Mr Perkin, in those patients having elevated metabolism and elevated blood iodine there is an incidence of 0.5 per cent recurrent hyperthyroidism, and when in those cases with elevated basal metabolism and normal or below normal blood iodine, there are 22 per cent recurrent hyperthyroidism, it becomes evident that radical subtotal thyroidectomy should be done in those patients with hyperthyroidism and low blood iodine.

Perhaps the most important single factor in the surgery of hyperthyroidism is the control of mortality. Our mortality figure for the entire 17,388 goiters is 0.76 per cent. We have been able to maintain a mortality rate ranging below 1 per cent constantly even in our worst years in all of our cases of primary hyperthyroidism. In toxic adenoma we have been able to maintain a mortality rate slightly above 1 per cent.

Control of mortality in our opinion has to do with preoperative preparation, the division of the operation into stages, the avoidance of postoperative complications, and the character of the postoperative treatment. There is little range of variation in the possibilities of patients' control in the preoperative preparation. One is limited in the control of the metabolism by rest and by attempting to accomplish involution of the thyroid gland by iodine and is likewise limited in the attempt to balance metabolism by the amount of carbohydrate which can be gotten in by mouth and by vein.

Mortality is, we believe, more definitely controlled by multiple stage procedures than by any other single factor in the surgery of hyperthyroidism. The available stages are ligation of the superior thyroid arteries, first stage hemithyroidectomy followed by second stage hemithyroidectomy. It has always been our experience as has been proved by articles which we have published on this subject that when we diminish the number of multiple stage operations which we do in a given year, the mortality

rate immediately rises. We have demonstrated in reporting 113 consecutive pole ligations that in 66 per cent of these cases there was an immediate drop in metabolic rate, a drop in pulse rate, and a gain in weight. When one realizes that a procedure of such little magnitude as pole ligation will accomplish this improvement in two-thirds of the cases, it is a measure to be seriously considered in any patient in whom there is doubt of his or her ability to withstand a first stage hemithyroidectomy. When one realizes likewise, that in 85 per cent of the cases in which first stage hemithyroidectomy has been done there was an immediate drop in metabolic rate, a drop in pulse rate, and a gain in weight one must seriously consider that in any patient in whom it is suspected that complete subtotal thyroidectomy may be dangerous, an 85 per cent chance of improvement in an operation of definitely less magnitude than subtotal thyroidectomy is to be considered.

The preoperative factors which would lead one to employ multiple stage procedures are marked weight loss, the occurrence of the disease in patients over fifty, in patients who have had the disease over a year or longer, in patients with low blood iodines, and with apathetic thyroid states. It should be realized that basal metabolism is the poorest criterion of operability of all of the factors associated with thyroid disease. The factors on the operating table which indicate severity of intoxication and danger of a fatality are the consumption of large amounts of oxygen, a progressively rising pulse pressure, and the occurrence of technical difficulties particularly with bleeding.

The two outstanding postoperative complications which in our opinion bring about fatalities in hyperthyroidism are postoperative hemorrhage and respiratory difficulties. Postoperative hemorrhage is a most undesirable complication to have associated with the surgery of hyperthyroidism. Postoperative hemorrhage produces fatalities because it occurs most often either on the same day of op-

eration when the patient has already been through a considerable ordeal or on the following day when they are in the stage of postoperative reaction. When it is necessary at such times to give these toxic patients an anesthetic to reopen their wounds and to put them through another operative ordeal, the additional burden is often just enough to bring about a fatality. It, therefore, is of extreme importance we believe to ligate every vessel in subtotal thyroidectomy with the idea in one's mind that caution is to be employed so that postoperative hemorrhages do not occur.

Another postoperative complication which plays a very great part, we believe, in the production of thyroid mortality is interference with breathing postoperatively. We have repeatedly stated that when patients have breathing difficulties while still on the operating table after the wound has been closed, the wound should then and there be reopened, that the difficulty should be found and corrected, and that such patients should not be sent back to bed with insufficient oxygenation.

To permit a patient after subtotal thyroidectomy for hyperthyroidism to pass through his first night after operation a little husky and a little hampered for air is to invite a fatality. Postoperative suboxygenation in patients who have been operated upon for hyperthyroidism often swings the balance in favor of a fatality. We have repeatedly written that when one begins to debate whether or not a tracheotomy should be done postoperatively in patients with hyperthyroidism showing postoperative breathing difficulties, that is the time to do it. There is no great disadvantage in tracheotomy provided the tracheotomy is properly done and placed at a proper level and it is often the procedure which swings the balance in favor of a recovery. Our laryngologists have demonstrated to us that there is a tendency on the part of surgeons to make tracheotomies too high. The easiest place to do a tracheotomy is relatively high, close to the cricoid. This is the point at which the trachea is narrowest and where

strictures are most likely to result. If tracheotomies are made lower in the tracheal ring there is no tendency to narrowing and immediate and spontaneous closure of the air fistula occurs as soon as the tube is removed. It is important we believe in patients with hyperthyroidism having postoperative obstruction to breathing to do early rather than late tracheotomy.

Conclusions

There is no serious aspect in the patient with borderline hyperthyroidism. The condition will settle itself much better with time and observation than with hasty surgery.

There are definitely patients with low grade chronic hyperthyroidism and with multiple colloid adenomas in whom subtotal thyroidectomy even in the presence of a normal metabolism, will give good results. These cases are, however, rare

and require most conscientious discrimination.

The reports up to the present of tissue culture cross grafting of parathyroids for tetany show little encouragement that it will be a successful procedure.

The incidence of injury to the recurrent laryngeal nerves is too high and can be materially lessened by the demonstration and dissection of nerves in every subtotal thyroidectomy.

Anesthesia is an extremely important factor in the surgery of hyperthyroidism. Intratracheal anesthesia, cyclopropane, and the employment of helium have marked real advance in anesthesia for thyroid disease.

Indications for the radical and conservative removal of thyroid tissue in hyperthyroidism are discussed, as also is the relation of multiple stage measures to mortality. The relation of hemorrhage and respiratory difficulty to mortality is also discussed.

A DOCTORS' CLUB AT THE BIG FAIR

Physicians and public health workers will have their own Professional Club, an incorporated organization, at the New York World's Fair of 1939, it is announced. Housed in the fair's Medical and Public Health Building, the Professional Club will be the first of its kind at any international exposition.

The Professional Club will occupy 5,000 square feet on the main floor of the Medical and Public Health Building, devoted to scientific and educational exhibits.

Accredited members of the American Medical Association and the American Public Health Association will be eligible for membership in the Professional Club. It is expected that membership will be extended to other professional groups.

The incorporators of the Professional Club are Dr. James R. Reuling, Jr., who has been elected president, Dr. Edward R. Cunniffe and Dr. Matthias Nicoll, vice-presidents, Mrs. W. R. Walsh, secretary, and Dr. B. Wallace Hamilton, treasurer. Dr. Alfred Hallman is chairman and Dr. John Bauer vice-chairman of the board of directors.

PROGRAM FOR SOCIAL HYGIENE DAY, FEBRUARY 1

The Bureau of Social Hygiene invites physicians to participate in the activities of Social Hygiene Day, February 1.

All sessions of diagnostic and treatment stations, and central office will be open to physicians who are invited to visit them. The facilities available to physicians in practice will be fully explained.

The special emphasis which the Bureau places on physicians' share in the control of Venereal Disease will be reviewed. Staff members of the Bureau will be available to answer questions and to explain any problems arising in the routine of drug requisitions and consultation appointments.

A meeting will be held at 125 Worth Street, New York City, Department of Health Building Conference Room, second floor at 8:30 P. M. Prominent guest speakers will participate.

Addresses of Social Hygiene centers and copies of the program may be secured by writing the Bureau of Social Hygiene, 125 Worth Street, New York City, or by phoning WOrth 2-6900, Extension 252.

THE KIDNEY FUNCTION IN HYPERTHYROIDISM

ELMER C. BARTELS, M.D., Boston

HYPERTHYROIDISM does not cause any important anatomic changes in the kidneys and the possibility of changes in function has received little attention. Yet the profound effects of thyrotoxicosis on other vital organs points to the need for careful scrutiny of changes in renal physiology under the metabolic strain of this disorder.

Mention of the effects of thyroid disease on the kidneys has been found in only three publications. In Means' recent book on *Diseases of the Thyroid*, he stated that pathologic changes were not noted in his cases except for slight vascular changes and an occasional hyalinized glomerulus. Observations on renal function were reported in two earlier papers. Lawrence and Rowe reported without comment the results of the phenolsulphonphthalein tests in a comparative study of hyperthyroidism and myxedema. In the former the average phthalein excretion in two hours was 59 per cent, in the latter 53 per cent. Lerman and Brogan found that the results of this test were negative in seventy-five cases of exophthalmic goiter, except for a slight diminution in excretion with older patients.

Further study of the problem was undertaken for two reasons. An effort was made primarily to obtain additional data concerning the metabolic effects of hyperthyroidism by using a more sensitive method to detect less apparent changes in renal function. Secondly, the information was desired to aid in interpreting the results of studies of the hepatic function recently made at the Lahey Clinic, using the hippuric acid excretion test of Quick. Briefly, this test consists of the administration of 5.9 Gm. of sodium benzoate, followed by the quantitative

collection of the urine for the next four hours and the determination of the hippuric acid in the specimen obtained. This study indicated that liver function undergoes a change in the presence of hyperthyroidism more frequently and to a greater extent than has previously been shown. After publication of these data the possibility that changes in renal function might affect results was suggested.

Kohlstaedt and Helmer studied the latter question. In a series of cases of hepatic disease they determined both the hippuric acid excretion and the urea clearance. They concluded that with a normal urea clearance test, a low output of hippuric acid indicated impairment of hepatic function. However, if the urea clearance was less than 50 per cent of normal, the diminished output of hippuric acid might be influenced by renal damage as well as hepatic disturbance. They stressed the advisability of performing both the urea clearance and hippuric acid tests so that the significance of the latter might be judged clearly.

Method

The urea clearance test was selected for this study because it apparently gives accurate and complete information regarding the functional ability of the kidneys. The urea clearance test of Van Slyke was used. Values between 75 and 125 per cent represent the normal range.

Twenty-three cases of hyperthyroidism were included in this study (Table 1). The only criterion for selection was absence of discernible renal or vascular disease, including hypertension. In all these cases the kidneys had the power to concentrate normally. Freyberg has shown that the value of the urea clear-

* Exophthalmic goiter

† Adenomatous goiter with hyperthyroidism

ance test is lessened in many cases after the concentrating ability of the kidney is diminished. This factor did not come into consideration in our series.

The test was made during the period of preoperative management. In a few instances two tests were made but usually one test sufficed as the results of repeated tests seemed to agree with those obtained first. Of the twenty-three patients, only three were males. Fifteen patients had exophthalmic goiter and eight patients, adenomatous goiter with hyperthyroidism.

Results

The results of a comparative study of those patients over fifty years of age and those forty years of age and under are given in Table 2. One half of those over fifty years had determinations below the accepted normal of 75 per cent, only three being over 100 per cent. The average was 85 per cent. In the group

forty years or under, only one patient had a determination under 75 per cent, with five over 100 per cent. The average was 100 per cent. These results compare with those obtained in the study of Lerman and Brogan who found a diminution in the output of phenolsulphonphthalein in older patients.

In Table 3 are shown separately the results of urea clearance in cases of exophthalmic goiter and adenomatous goiter with hyperthyroidism. Although the average urea clearance is somewhat different in the two groups, 94 per cent and 82 per cent, respectively, this difference may be related to differences in the ages of the patients, the average age of the patients with exophthalmic goiter was thirty-nine years as compared to fifty-one years in the group with adenomatous goiter. Thus, there does not appear to be any significant difference in the urea clearance in the two groups of patients.

In Tables 4 and 5 the results of the

urea clearance in groups divided according to the duration of hyperthyroidism and amount of weight loss during the disease are given. Apparently neither of these factors played a rôle in the alteration of renal function. Likewise, no apparent relationship was found to exist between the level of the basal metabolic rate and the urea clearance, as indicated in Table 6. Five patients had mild grades of secondary anemia (cases 3, 6, 11, 22, and 23) but this did not seem to hinder the normal renal function as some of the highest urea clearance determinations were obtained in those patients.

with low grades of anemia. The pulse pressure had no direct relation to the urea clearance as judged by a rough comparison.

It is of greatest interest to see if there is impairment of renal function in the most severe cases of hyperthyroidism. The severity of the illness is indicated by the type of operative procedure selected. Subtotal thyroidectomy in one operation is employed in most cases. Subtotal hemithyroidectomy in two stages, is employed in the more serious cases and this is preceded by pole ligation in a few of the most desperately ill patients. Therefore, if there is any change in renal function at all, one should look for it in the latter cases. Table 7 shows, however, that the type of operative treatment had

no relation to the result of the urea clearance test. In the two cases in which preliminary pole ligation was required before thyroidectomy was done, renal function was unimpaired, in fact, in these cases the urea clearance was high.

Summary and Conclusions

This study presents evidence to show that hyperthyroidism, as such, no matter how severe, does not affect or alter renal function as determined by the urea clearance test. In only six cases out of twenty three was the determination be-

low the range of normal. In all cases the change was of a minor degree, since five of the six occurred in patients over fifty years of age, this change can be explained as some minor vascular renal disturbance common to patients of this age. No relationship was found between the urea clearance and the type of hyperthyroidism (either exophthalmic goiter or from adenomatous goiter), duration of dis-

ease, weight loss, level of the basal metabolic rate or severity of the disease as indicated by the type of operative procedure employed.

This conclusion seems to bear out the clinical opinion that patients with hyperthyroidism in the absence of cardiac failure or pre-existing nephritis tolerate an abundance of fluid given by the intravenous route. The results also probably disprove the presence of an hepatic-renal syndrome for in spite of severe degrees of

CONCERNING OXYGEN-WANT IN PILOTS FLYING AT 12,000 FEET ALTITUDES

ALVAN L. BARACH, M D, New York City

THE effects of moderately high altitudes, such as are used frequently in civil and military aviation, on the pilot's judgment and other mental functions have been recently made the subject of discussion and supposed controversy between investigators in this field.¹ In the interest of a more correct interpretation of the evidence and the views of the investigators involved, the following excerpt from an article published in the official journal of the Aero Medical Association of the United States is presented²

'The present study is concerned with the effects of a 4 hour sojourn in a simulated high altitude of approximately 12,000 feet (low oxygen chamber) on a complex mental function, as solving problems on a slide rule. Such an investigation seemed relevant to the possible effects of oxygen want on reasoning and judgment. The physiologic and psychologic effects of relatively mild degree of anoxemia have been made the basis for the suggestion by Barach that oxygen inhalation be employed at altitudes of 10,000 and 12,000 feet or over in aviation. It is now recognized that the rebreathing tests on pilots during the World War gave a distorted impression of the effects of oxygen deprivation on mental reactions. In these tests each pilot rebreathed a certain amount of oxygen, so that the point of collapse was reached within twenty to thirty minutes. By exerting great effort, the average pilot would not show marked impairment until just previous to collapse, thereby giving a false impression as to the altitude which might be tolerated over several hours.

'Numerous experiments in low oxygen

and low pressure chambers and with rebreathing devices at sea level have demonstrated that mental impairment is manifested at oxygen partial pressures corresponding to relatively low altitudes, well in advance of impending collapse as stated by Dunlap. In a low pressure chamber Wilmer and Berens found that there was slight impairment in the more delicate visual functions at 12,000 to 15,000 feet. This has recently been confirmed in experiments involving the photographing of eye movements under anoxemia. Tanaka, working with Halldane in a low pressure chamber at Oxford, observed a sudden decrease in efficiency in mental and physical work at 15,000 feet, or 425 mm of pressure. In Barcroft's low oxygen chamber at Cambridge, Lowson found a significant decrease in mental tests when the diminution of oxygen reached approximately 50 per cent of the normal, or 15,000 feet. In trans-Andean flights, during one half an hour at 14,000 and 10,500 feet without oxygen, McFarland observed a decrease in mental flexibility and in capacity for simple mathematical problems. In a more extensive investigation of the effects of prolonged flights at altitudes ranging between 8,000 and 12,000 feet on trans-Pacific flights, McFarland and Edwards found only slight impairment in the crew of eight airmen at the highest altitude reached. The observed differences did not show statistical reliability. They attribute the high degree of mental alertness in the airmen at those altitudes to the acclimatization attained during the long flight of 126 hours in the air, covering 14,000 nautical miles. Flack suggested to members of the Royal Air Force that

(From the Department of Medicine, Columbia College of Physicians and Surgeons and the Presbyterian Hospital)

oxygen should be inhaled even at relatively low altitudes to prevent fatigue during military operations."

The final conclusion of this paper was as follows:

"There were perceptible differences in behavior and a greater frequency of subjective ailments in the low oxygen series compared with air. The two subjects who were physically unfit experienced numerous ailments such as headaches and dizziness and they had greater difficulty in concentrating. They worked very quietly throughout all of the series. The other two subjects, who were in good physical condition, were more boisterous and talkative in the low oxygen series compared with air."

"The results of these experiments and the others reviewed above suggest that airmen would be benefited by inhaling oxygen at 12,000 feet or over in maintaining a higher degree of mental efficiency. Since men in poor physical and mental condition are especially sensitive to anoxemia, the inhalation of oxygen would be especially indicated in those instances."

In the report referred to of McFarland and Edwards³ the average altitude was 9,460 feet. Evidence of acclimatization was proved by the increase in the number of red blood cells found in these airmen. However, the Brightness Discrimination Test which gives an objective measure of diminished sensitivity of the retina to light stimulation under anoxemia showed a "slight yet consistent diminution at 10,000 to 12,000 feet, similar to results obtained in chamber studies at sea-level." The existence of *slight* degrees of impairment at altitudes of 8,000 to 12,000 feet is consistent with the view that a high degree of mental efficiency may be maintained under the most *favorable* conditions, in pilots who have had the opportunity to acclimatize. However, this does not indicate that these airmen maintain the *highest* degree of mental efficiency. Furthermore, it is freely acknowledged that the acclimatized airman only shows a favorable response to tests of his mental and bodily

functioning when he remains at rest³. "If one engages in overt physical activity, as may be observed in a steward while actively engaged in serving meals, at 11,000 to 12,000 feet, the pulse rate may be considerably increased, slight cyanosis and fatigue may be observed, as well as heightened temperamental reactions."

Conclusions

1 In short flights, both in military and commercial aviation, no evidence of acclimatization to low oxygen atmospheres has been demonstrated. The exposure of pilots to altitudes of 10,000 to 12,000 feet produces an anoxemia which may be compared to intermittent carbon monoxide poisoning, such as may occur in poorly ventilated garages.

2 The damaging effects on the mental and bodily functions of the unacclimatized individual after exposure to an altitude of 15,000 feet, in which the oxygen pressure of the atmosphere is approximately 50 per cent of the normal, have been described by many physiologic investigators. More sensitive tests of cerebral function at altitudes of 12,000 feet reveal that judgment and emotional control may be distinctly impaired with this degree of oxygen-want, and, furthermore, that this type of impairment is aggravated by (a) physical activity, (b) physical unfitness, (c) nervous conditions, especially in psychoneurotic individuals, and (d) the ingestion of alcohol.

3 A review of the experimental data now available leads to the conclusion that pilots, both those engaged in military as well as civil aviation, deserve protection from repeated exposure to that degree of oxygen-want which is experienced at altitudes of 10,000 to 12,000 feet and over by suitable administration of oxygen. The point of view which denies the advisability of oxygen administration until such altitudes are reached which seriously threaten the conscious mental functions seems opposed in principle to our present program of public health in other industries. These considerations do not

apply to the average passenger hut only to those in whom the presence of certain types of cardiac and pulmonary disease interferes with their capacity to acquire additional oxygen from a rarefied atmosphere.

PRIZE ESSAYS

of the Medical Society of the State of New York

The Merrit H. Cash Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York to be held April 24, 1939, in Syracuse, New York.

This prize of ONE HUNDRED DOLLARS will be given to the author of the best original essay on some medical or surgical subject.

Competition is limited to the Members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed

Essays shall be typewritten or printed and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer.

If the Committee considers that no essay or contribution is worthy of the prize, it will not be awarded.

All essays must be presented not later than April 1, 1939, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 2 East 103rd Street, New York City.

FRANK B. CROSS, M.D., Chairman
Committee on Prize Essays

FRANCE DWINDLING

If the present drop in the national birth rate continues, the population of France in fifty years will drop from 40,000,000 to 28,000,000. Deaths exceeded births by 14,000 in 1937, when foreign emigrants were included in the tabulation and by 30,000 for French families alone. The national birth rate in 1876 was more than 1,000,000 as compared with 610,000 in 1937. During this period the average duration of life has increased from forty-five to sixty years. At the present rate France will lose 100,000 inhabitants a year and in another twenty years the loss will reach 200,000 a year. Meanwhile, in the totalitarian states the birth rate is increasing. There were 861,000 more births than deaths in 1937 in Italy—J.A.M.A.

ARE WE CIVILIZED, OR WHAT?

The qualifications of a quack recently arrested in Connecticut consisted entirely in his double and triple joints, together with the fact that he was the son of a seventh son and born under a veil known in the old vernacular as a caul. He reports the *New England Journal of Medicine*. He had supplemented his natural proficiency with some reading in books obtained through correspondence courses and was said to have taken a one-year course in a so-called medical school in Chicago but he obtained most of his knowledge from a manual published by a nationally known patent medicine company. His diagnoses were of course guesswork; his favorite verdicts were high blood pressure and gastric ulcers.

REPORT OF A CASE OF BOECK'S SARCOID WITH CONSTITUTIONAL SYMPTOMS, EYE, GLANDULAR, PULMONARY, AND SKIN LESIONS

LEWIS FOX FRISSELL, M D , and WILLIAM T MEDL, M D , New York City

THIS patient was first seen on May 4, 1934, in the eye clinic complaining that she had had pain and poor vision in the right eye for two weeks. She was found to have iritis, sinusitis, and abscessed teeth. Her tooth was pulled and her sinuses irrigated in the clinic but her iritis became no better.

She was admitted to the eye service on May 28, 1934. Her ear drum was incised because of bulging but no pus was obtained. X-rays of her sinuses were negative. Right mastoid looked congested. Her eye showed iritis with posterior synechiae. Her temperature over an eleven-day period ranged up to 101 F daily. She was discharged to be again followed in the clinic.

She was admitted to the medical ward on June 16, 1934. She complained of vague abdominal pains and pains in her right knee, shoulder, and elbow. She had continued to have difficult vision and headache. Her past history and family history were completely negative.

Physically she was a well-developed and nourished young adult female who was very apprehensive. Pupils were large and fixed. There was slight conjunctival congestion and vessels could be seen in the iris. There was tenderness over the frontal and maxillary sinuses and over the tooth socket from which three weeks before an abscessed tooth had been removed. There was slight enlargement of all the cervical glands and slight general abdominal tenderness especially in both lower quadrants. No skin lesions or joint tenderness were manifested.

Temperature ran from 100 F to 101 F daily. Urine was clear. Red cell counts and hemoglobin were 4.7 million and 83 per cent. White count was 6,500 with 74 per cent polys, 22 per cent lympho-

cytes, 2 per cent eosinophiles, and 2 per cent monocytes. Sedimentation rate was normal. Sinuses were clear on x-ray. The tooth socket was irrigated and was negative on x-ray. X-ray of the chest showed enlarged glands in each hilar region which were interpreted by the roentgenologist as suggesting the possibility of Hodgkin's disease.

Agglutinations were negative for typhoid, paratyphoid A and B, abortus, and mellitensis. Wassermann and G C fixation tests were normal. Tuberculin tests with human and avian tuberculin were negative. Urinalyses were consistently negative. Leucocyte counts were on the low side of normal usually being below 7,000, with usual percentage of 65. Eosinophiles averaged about 2 per cent but ranged from none to ten. Blood chemistry was normal including total protein, serum albumin, and globulin ratio. Stools contained no pathogenic bacteria, ova or parasites and no occult blood. Repeated x-rays of sinuses and mastoids showed nothing. Gastrointestinal x-ray series were normal. X-ray of chest showed no change in three months.

During her stay of five months, her temperature fluctuated up to 101 F for the first three months and gradually came down to normal. She was given typhoid vaccine intravenously resulting in three chills, with no effect. Her eyes were aching this whole period and she was partially blind. She was given deep x-ray therapy to her mediastinal nodes to see if they were radiosensitive but no change was noticed. After five months, she was discharged with some improvement in her vision but with fixed pupils and posterior synechiae, and floating opacities in the vitreous.

In December, 1934, and January of

1935, the patient was again in the eye ward with flare-up of her iritis. X ray of her chest at this time showed that her hilar glands had receded but that the hilar markings were accentuated. She was then not seen until May, 1936, one year and four months later. She complained of a swelling in her inguinal region and came to the hospital for a hernia repair.

August 17 1934

Because of her previous history, she was admitted to the medical ward for check-up. Some skin lesions were noted which had been present for some time but no exact time was remembered by the patient. They were scattered over her arms and legs with a few on her forehead. They were bluish red, firm, nontender, and varied in size from one half to one cm. Her eyes were as on her previous admissions, fixed pupils, vitreous opacities and posterior synechiae. She had some abdominal tenderness in her right lower quadrant. X ray of the chest showed a shotty infiltration throughout both lung fields and no evidence of the enlarged hilar nodes previously seen.

July 18 1936

Diagnosis of Boeck's Sarcoid was made and confirmed by biopsy of a nodule on the forearm.

Her hernia was repaired under local anesthesia.

Boeck¹ described the condition in 1890 and made histologic examination. He gave the disease the name of sarcoid on account of its resemblance to the small cells of sarcoma, he later believed that the disease was a peculiar form of tuberculosis and termed it "benignes miliar-lupoid."

Not until after the turn of the century, however, was it recognized that this disease did not affect the skin alone. Kienbock² in 1902 described bone changes.

September 13 1937

due to this disease which is more elaborately described by Jungling³ in 1925 Banzancon and Labbe⁴ in 1911 first described lesions in the lymphatic system, particularly of the lymph nodes, while Kuznitzky⁵ in 1915 first described lung changes. While since this time, sarcoid, as a generalized disease, has been thoroughly recognized, this knowledge has perhaps not been as widely disseminated

May 28, 1936

May 28, 1936

being arrived at only upon a second admission to the hospital a year later, when she came in for operative hernia repair, and incidentally the typical violaceous, firm, nontender skin lesion was discovered and the correct diagnosis made by pathologic examination.

Our case illustrates admirably the febrile type with eye, lung, and deep gland involvement but did not show the bone changes which are said to resemble

as the literature deserved. Many clinicians still regard it as a skin disease. The case we have presented admirably illustrates a disease starting with an iridocyclitis, affecting the mediastinal lymph nodes and later the lung, showed no skin lesions until long after her convalescence from the acute febrile process, which, in itself, lasted four months, during which time many erroneous suggestions were made as to the cause of the fever: sinus, ear, tuberculosis, Hodgkin's disease, the correct conclusion

May 28, 1936

a leprous bone more than any other condition or the final stage presenting the punched-out appearance in the plate which is commonly associated with gout. It also did not show the superficial glandular enlargement except for very slight involvement of the cervical glands on her first admission to the hospital, which was thought to be secondary to tooth infection. Etiologically, dating from Boeck,¹ largely on the ground of the resemblance of the lesion to tubercles, the disease has been considered a form of tuberculosis. Except for this, however, as admirably described by Longcope⁶ there is little evidence definitely implicating the tubercle bacillus. Tuberculin reactions, human, bovine, and avian are negative and injections into guinea pigs do not produce tuberculosis.

Led by analogy to lymphogranuloma inguinal, Williams and Nickerson⁷ prepared an antigen from the sarcoid tissue which in four cases produced skin reactions within twenty four hours, by intradermal test. The diagnosis of sarcoid was proved in two cases by splenectomy and in the other two cases by resections of the intestine, which microscopically showed the characteristic sarcoid lesion. These authors suggest that, as in the case of lymphogranuloma inguinal, sarcoid is probably also a virus

disease and if this work be substantiated on a larger series of cases, it would seem a far more rational explanation than an atypical tuberculosis. The use of this antigen may also enable us to make a positive diagnosis before the appearance of skin lesions and puzzling pictures such as is presented in our case with prolonged fever, be diagnosed by a skin test. The diagnosis at present, is easy if the skin lesions are present. These are characteristic violaceous, nontender skin lesions and show no tendency to break down and can be readily proved by biopsy. The glandular enlargement, however can readily be mistaken for Hodgkin's disease, lymphosarcoma, or tuberculous glands.

The pulmonary complications can be readily taken for tuberculosis, frequently of the milky type. The eye condition can be readily mistaken for any toxic or tuberculous lesion causing similar symptoms.

EXAMINATIONS IN OPHTHALMOLOGY CHANGED

The American Board of Ophthalmology announces an important change in its examination of candidates for the Board's certificate.

Examinations will be divided into two parts. Candidates will be required to pass a written examination held simultaneously in cities throughout the country on March 15 and August 5. Oral examinations will be held at St. Louis May 15, Chicago October 8.

Applications for permission to take the written examination March 15 must be filed not later than February 15. Application forms and detailed information should be secured at once from Dr. John Green, Secretary 6830 Waterman Ave. St. Louis Mo.

RUSTICATING THE YOUNGSTERS

Poland has passed a law regulating the practice of newly graduated physicians whereby for two years they may practice only in rural areas or in towns with a population less than 5,000.

The purpose is to relieve the congestion of physicians in the large centers.

The Sixteenth Annual Meeting of The American Orthopsychiatric Association, an organization for the study and treatment of behavior and its disorders will be held at the Commodore Hotel, Lexington Avenue and 42nd Street New York N. Y. on February 23, 24 and 25 1939. Dr. Norville C. LaMar, Secretary 149 East 73rd Street, New York N. Y.

DRUG THERAPY IN SOME COMMON OTOLARYNGOLOGIC CONDITIONS

RALPH ALMOUR, M D , F A C S , New York City

THIS century has witnessed a rapid advance in the therapy of disease. The gains have been accomplished mostly in fields far removed from drug therapy. The more exact knowledge of the uses to which the biologic preparations lend themselves has resulted in the removal of many diseases from the list of hitherto incurable lesions. The enormous strides which have been made in vitamin therapy have further reduced materially the incidence of such maladies as rickets, scurvy, beriberi, pellagra, etc., and have furnished the physician with additional armamentarium in his treatment of the sick. All this has to a large extent tended to throw into disrepute the use of drugs in the treatment of disease. Intimate contact with the more recent graduates in medicine has convinced us that they have but a limited knowledge of the efficacy of drugs. On the other hand it often has been a source of amazement to us to see the beneficial results of a little-known drug suggested during consultation with an older practitioner rich in bedside experience. "Conclusions on its effectiveness are largely a matter of clinical interpretation, with all the opportunities for error which one may attribute to personal equation, and perhaps to personal prejudice. Drug therapy is largely bedside therapy, where the life involved is a human life, where phenomena, of which we may know but little, occur in a variable subject, the human individual with a disease."¹ In order that otolaryngology may not completely discard the efficient service which certain drugs in the past have rendered it, this paper sets forth the personal experiences of the writer with some of them. There is herein contained nothing which is new, even though to some it may appear new. It will be based largely upon clinical ob-

servations, pharmacologic substantiation, where available, will be presented. It is hoped that others will detail their observations along similar lines to the end that this valuable branch of therapeutics may be perpetuated.

Tonsillectomy in Rheumatics—One is frequently called upon to remove the tonsils in a person suffering from subacute or chronic rheumatic fever. In such cases it has been established previously that the tonsils are the source of infection. Any disturbance of the local focus of infection, such as may occur during surgery, is apt to liberate into the system a large amount of toxins which will cause an acute exacerbation of the disease. To forestall this, it is advisable to administer sodium salicylate on the evening before tonsillectomy. Two hundred grains (200) dissolved in boiled starch solution should be administered by rectum.¹ This should be continued for five to seven days postoperatively. Despite the fact that the use of salicylates in rheumatic fever and its allied conditions is still empirical, its value in this connection has convinced us of its ability to obviate flare-ups of the disease due to tonsillectomy.

Small Doses of Quinine—Following mastoidectomy for acute suppuration, it sometimes happens that a low-grade temperature associated with a secondary anemia will persist for several weeks. We have found that this can be corrected quickly by the use of small doses of quinine. In a child below five years of age, quinine sulfate, grains $\frac{1}{2}$, t i d, and in older persons grains 1, t i d, will result in a return of the temperature to within normal range and an increase of the red cell and hemoglobin content of the blood. While here used also empirically, clinical trial has demonstrated

that quinine does stimulate the hematopoietic function of the marrow. In adults, the addition of thyroid extract, grains $\frac{1}{10}$ per dose, stimulates metabolic function, and enhances convalescence.

Dermatitis Following Mastoidectomy—The irritation of the skin surrounding the postauricular incision which is so often noted following mastoidectomy is the result of irritation due to the exudate coupled with the lack of evaporation of the sweat due to the applied bandage. A foul odor develops within twenty four hours after the change of bandage. All this can be obviated by the use of a liberal application of lanolin ointment before a new outer dressing is applied. Better still is a boric acid ointment with a lanolin base. An excellent preparation, one which has given us uniform satisfaction, is Borofax.

Drugs in Tinnitus—While we know fully well that tinnitus cannot be cured by the administration of drugs, nevertheless there are instances where it is possible to achieve an appreciable diminution in the intensity of the head noises with the aid of drugs. The older literature is full of references to the value of certain preparations which have now largely been discarded. The writer's experience is limited to the use of a few of them in certain types of tinnitus.

Where, either through overwork or because of a secondary anemia, tinnitus has become unbearable, a striking improvement will in some instances be obtained by minute doses of quinine. This is preferably administered in capsules, as follows:

| | | |
|---|-----------------------|-----|
| R | Quinine hydrochloride | 0.1 |
| | Sacch. lactis | qs |
| | m et f cap no X | |
| | Sig. One t. i. d. | |

This was first suggested by Jacobson.² Caution must be exercised in giving quinine to a deafened person for the relief of tinnitus. If instead of a reduction in intensity, the tinnitus becomes aggravated the drug should be stopped immediately. In this connection, it is of interest to note that Urbant-

schitsch³ brought about an immediate cessation of a severe tinnitus due to quinine ingestion by the use of amylnitrite.

The bromides have been more generally used for the relief of annoying tinnitus. With these, the writer has obtained his best results with dilute hydrobromic acid. This can be given in 10 to 15 drop doses three times daily, in a half tumbler of water. Since even in this dilution there is danger of injury to the enamel of the teeth, it is advisable to rinse the mouth with a dilute solution of sodium bicarbonate. There is some pharmacologic basis for the use of quinine and bromides in tinnitus. The former has a definite effect on the cochlear end organs, and will produce a nerve deafness when given in large doses. Its favorable action on tinnitus, when given in minute quantities, may be the result of a sedative action on the nerve endings. Bromides act directly on the nerve mechanisms and diminish the symptoms of nervous irritation.

Following the favorable results obtained by Furstenburg in the management of Ménière's disease by alteration of the water metabolism, the writer has employed ammonium chloride in some cases of intractable tinnitus with a resultant marked diminution in intensity of the subjective headaches. Twenty (20) grains, three times daily, may be tried. In otosclerotics, this should be combined with potassium iodide, 15 grains daily.

In older people, particularly in those who complain of a pulsating type of tinnitus, tincture of digitalis, 10 drops three times daily, often results in complete cessation of the symptom.⁴

Acute Laryngotracheitis—This is an inflammatory disease of the larynx, most commonly met with as a complication of the common cold. Very often, however, as happens in singers, teachers, and others who are apt to overuse their voice, a hyperemia of the mucosal lining of the larynx and subglottic regions occurs with a resultant hoarseness, painful phonation, and extremely irritative cough. In the early stage of the disease,

the violent expulsive efforts of this dry, hacking cough exhaust the patient and produce severe discomfort. The usual treatment of rest in bed, inhalations of medicated steam, and the external application of cold to the throat will bring about relief in three days

It is, however, possible to bring relief within a short period of the onset of the disease by the following therapeutic regime. During the past ten years, the writer has followed the recommendations of Neff¹ for the early stages. He prescribes " $\frac{1}{8}$ grain of pilocarpine nitrate in 1 oz of distilled water. Give one teaspoonful every hour for three doses, then every four hours for three more doses, and stop. It will begin to produce moisture of the mucous membranes of the larynx, relieve the pain, and promote expectoration within one hour from the initial dose." To allay the irritating cough during this period of medication, codeine may be given in addition.

Once secretion has been established and the cough has become productive, the facilitation of expectoration and the relief of spasm, preferably without the use of narcotics or the barbiturates, should be started. Here, the more drastic expectorants, such as the emetics (apomorphine, ipecac, or antimony) need not be used because they stimulate secretion from not only the laryngeal and bronchial glands, but also the salivary and sweat glands are stimulated either by direct action on their centers, or reflexly.⁵ For the purpose of promoting expectoration, an excellent drug is the fluid extract of thyme.

Following the stopping of pilocarpine, should be given

R Fl Ext Thyme 1 drachm
Syr Pruni Virg
Aqua Dist aa $\frac{1}{2}$ drachm
D T D in doses no xxiv
Sig 3u q. 2 h

Clinically, this drug, when given before the bronchial secretions become thickened by the exudation of the products of inflammation, will ease the efforts needed to expel the secretions. It prevents the

appearance of a viscous discharge which clings to the walls of the larynx and trachea, and makes the cough spasmodic. The cough thus becomes an act of volition, resembling more the ordinary clearing of the throat.

The exact pharmacology of thyme is still a matter of dispute, and unfortunately little interest has been displayed in its use during the past few years, although it had been widely prescribed by physicians during the past few decades, its presence in the proprietary cough remedy Pertussin may, to a large extent, have prejudiced many doctors. Busby, Bliss, and Ballard⁶ consider it an antispasmodic. Gordonoff and Janett⁷ have demonstrated by animal experimentation that thyme in large doses acts both as a secretomotor and secretolytic drug. Misgeld,⁸ on the other hand, disagrees with Gordonoff's investigation since he feels that no exact method at present is at hand to determine experimentally the value of an expectorant. Only clinical trial, he feels, will determine the secretomotor or lytic effect of a drug used for the symptom of cough. With this the writer is in thorough accord. As Neff states "At present, it cannot be required that all drugs used in clinical practice have a justification for their use in accurate laboratory experimentation. Where such a basis is available, well and good, where it is not, the clinician must, as of old, use as his own laboratory, his patient, with his own equipment, namely, his senses and reasoning power." In the drug regime outlined for the rapid relief and the shortening of the course of acute laryngotracheitis, there are combined a drug (pilocarpine) whose pharmacologic action is known experimentally as well as clinically, and another drug (thyme), the efficacy of which as a medicament to keep the laryngeal secretions liquefied, can be proved by clinical trial (Beck,⁹ Saphra¹⁰).

In singers and public speakers, the combination of pilocarpine nitrate and fluid extract of thyme from the onset, discarding the first drug after the sixth

dose, will materially enhance the return of the normal voice. Where the disease is afebrile and is due to irritation alone, a return to normal can usually be expected within forty eight hours or less. In addition, of course, the usual local methods of therapy should be utilized.

Otomycosis—This lesion of the external auditory canal will usually respond to a 2 per cent solution of salicylic acid in alcohol. In a case which did not react favorably to this after a two weeks trial, the writer obtained a cure with a 3 per cent solution of copper sulfate in distilled water, instilled into the external canal after removal of the secretion and a thorough drying of the lining skin. This was first suggested by Valentin.¹¹ The canal was filled with the solution which was allowed to remain *in situ* for one-half hour, four times daily. Repeated mechanical cleansing of the canal each day and continued use of the copper solution resulted in a cure in five days.

To Check the Common Cold—Until the exact determination of the cause of the common cold is known, there will be no specific remedy to prevent it. Fortunately, however, it manifests itself very early by a dryness of the mouth, tickling sensation in the oropharynx, and a feeling of pressure over the glabella and frontal sinuses. When seen during this stage in an adult, it can usually be aborted by the following measures: rye whisky, USP, 4 ounces, should be mixed with an equal part of lemonade (juice of one and one-half lemons), and the rest water. This should be thoroughly chilled with out the addition of ice. With the feet in a hot mustard bath, the patient should be instructed to drink half of this mixture leisurely over a fifteen minute period. Then Dover's powder, grains v, should be taken internally, followed in the next ten minutes by the rest of the alcoholic beverage. He should then go to bed, adequately covered. This remedy is not only effective by virtue of its stimulation

of the sweat glands, but, because of its soporific effect, it enables the body forces to concentrate on the local infection in the rhinopharynx. Furthermore, the patient experiences no discomfort from the sweating since he will be in a sound sleep while this is going on.

Should the patient be first seen where the pharyngeal irritation has produced an irritative cough, the following prescription will be found of value in allaying the cough and dryness of the throat.

 M et Sig —5i q 3 h

In this brief summary of some useful drugs in otolaryngology, the writer has merely presented the high lights in their use in certain common conditions met with in everyday practice. Many others in our field have had similar experiences with these and other remedies, and the writer feels that they should be more fully emphasized. The custom, lately, it seems, is to delegate to the 'detail man' of a pharmaceutical concern the instruction of the coming generations of physicians in the use of drugs in the treatment of disease. This can only be stopped by a free interchange of our clinical experiences in practical therapeutics.

"STATUS THYMICOLYMPHATICUS"

Unusual Clinicopathologic Observations

TYREE C WYATT, M D , Syracuse

THE term "status thymicolymphaticus" is usually used as an anatomic diagnosis of the pathologist to indicate, for want of a better and more accurate way of description, a group of anatomic findings in individuals who have suddenly and unexpectedly died. This occasionally occurs in young adults but is strikingly much more common in infants and children who have given no recognized indication of the impending tragedy.

The first two cases which I shall briefly review represent this group and are reported only because of the fact that they occurred in the same family, at about the same age. The multiple occurrence in families is not uncommon in the literature, and this in itself is an interesting fact so far as suggesting possible underlying mechanisms.

Case Reports

CASES 1 and 2 J W, age five months and N W, age six months (28 15 and P A 32 1 $\frac{1}{2}$), females, died suddenly four years apart without evidence of previous illness. The histories of an older male child, the father, and the mother have failed to reveal any facts which seemed important in this connection. There were pathologic examinations on both infants at the request of the parents and the sole findings of lymphoid hyperplasia and small adrenals were recorded as status lymphaticus. The thymus in neither infant was strikingly large.

The next two cases I wish to describe in some detail for three reasons (1) They also were female infants of about the same age in the same family (2) One of them was observed over a period of two months because of attacks of un-

consciousness and collapse and finally was found dead in its carriage (3) The second baby at the age of 3 $\frac{1}{2}$ months, nineteen months after the first baby's death, began to have the same kind of attacks as the first, but still survives.

CASE 3 The history of the first baby (N L) is as follows. At about four months she showed signs of a rather marked coryza which later developed into definite pertussis. After four weeks the cough had markedly subsided. At about that time (about five months of age), she began to have periods of unconsciousness which the mother called "fainting spells." These came on suddenly and lasted approximately from one to ten minutes. Their onset was evidenced by a gasping cry which would attract the mother's attention even in another room, then the baby would lapse into unconsciousness associated with pallor and flaccidity but no cyanosis. As consciousness returned after a period of one to ten minutes, there was always marked flushing and profuse perspiration. When seen at the end of one attack there was no evidence of disturbance of cardiac rate or rhythm. Sugar determination on defibrinated blood taken at this time (2 $\frac{1}{2}$ hours after formula feeding) was 73 mg. The test was repeated at a later time when she had no seizure and was found to be 72 mg.

After the seizures the baby would seem a little dull and listless for a few hours and then would appear normal. She continued to have these spells over the next two months, as many as two or three on some days. There was nothing unusual about the blood count. X-ray showed a thymus which was perhaps somewhat larger than average but not strikingly so. However,

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, May 10, 1938*

we were already impressed with the possibility of any of these attacks terminating fatally and it seemed advisable to radiate the thymic area. One treatment was given in the hospital but they did not report for more treatments. The attacks continued after leaving the hospital but seemed somewhat less numerous and perhaps somewhat shorter, although the mother's observations may not be entirely reliable. She was inclined to minimize them and my contact with the case during the next six weeks was not very close. The report was that in the week before the baby was found dead it had seemed normal except for one short attack. At no time in any of the attacks was there any suggestion of choking. At the time of death it was seven months of age.

Pathologic Findings (P.A. 33.2) — Generalized prominence of lymphoid tissue in lymph nodes, intestine, and spleen. Thymus weighed 27 Gm. Irregular bluish red area of apparent atelectasis in right upper lobe. No foreign material in bronchi. Adrenals seemed smaller than usual and quite thin. Brain and pituitary and thyroid without gross lesion.

Microscopic Findings — Lymphoid hyperplasia. Very slight inflammatory reaction in lung in the area of atelectasis in right upper lobe. No definite changes in adrenals.

CASE 4 J.L., the second baby, born sixteen months later, also began to have periods of unconsciousness at the age of 3½ months which the mother felt were identical in every way with those of the first baby. The subsequent flushing and perspiration were also present. The age of onset in each was about the same. X rays of chest did not show any evidence of enlarged thymus. Blood chlorides 480 mg NaCl, Ca 10½ mg, sugar 11½ mg. During ten days' observation in the hospital there were four x ray treatments of the thymic area (¼ skin unit at each dose). She continued to have periods of unconsciousness after she went home, perhaps averaging two or three a week, lasting from five to forty minutes. They moved from Syracuse when the baby was

about one year old, but the mother has written that her last and longest attack was about one year ago. She is now 3½ years old and is reported to appear normal in every way.

The next two cases are infants in the third year of life who came to autopsy after having been ill only a few hours, presenting an obscure clinical picture characterized by convulsions and vomiting.

CASE 5 The first of these was admitted to Syracuse Memorial Hospital four hours before death. Past history was negative except for convulsions which began on the third day after birth and continued on the next day. There were some twitchings on the fifth day but after that she seemed normal in every way. Spinal puncture showed a bloody fluid. Since that time she had seemed well and normal in every way until the day of admission at two years of age when she had eight convulsions and vomited several times. During the four hours in the hospital before death she was in almost continuous convulsions. Temperature was normal. Acetonuria four plus.

Pathologic Findings — Thymus weighed twenty-two Gm. There was moderate prominence of the mesenteric lymph nodes. Both adrenals were enlarged and nodular and, microscopically, showed extensive replacement of the central portion with necrotic material which was partially calcified and in places showed true bone formation with bone-marrow spaces. There was considerable yellowish brown pigment, probably hemosiderin, which suggested that there had been at some time previously, presumably at birth, a large hemorrhage into the central portions. Around this central mass there was an irregular zone of cortical tissue, although in certain places it was very narrow or absent. No medullary tissue whatsoever was seen in the sections (Fig 1). The lungs showed slight bronchitis and bronchiolitis with slight evidence of bronchopneumonia. Neither the spleen nor the lymph nodes showed any evidence

FIG 1 Case 5

Photomicrograph of adrenal. Zone A consists of the remnants of the cortical layer which in places was entirely missing. Zone B consists of fibrous connective tissue with bone formation and scattered phagocytes containing hemosiderin. The upper portion of the section consists of structureless necrotic material. The dark mass represents calcification. ($\times 54$)

of toxic necrosis in the lymphoid nodules. There was some edema of the brain, but no evidence of birth trauma. The thyroid, pituitary, pancreas, and thymus sections showed no definite variation from the normal.

Because it is almost identical with the above case, I wish to refer briefly to a case which Drs. Wolbach and Wilson studied at autopsy at the Boston Children's Hospital in 1922. Dr. Wilson has kindly given me permission to review the case record. Both of these cases may be reported in more detail by him at a later time.

CASE 6 This baby was a female, age two years and seven months. Her history was unimportant until the morning of the

day of admission to the Children's Hospital. She waked at 7 A.M., stood up in bed, and fell unconscious. She remained unconscious until death fourteen hours later. There were numerous generalized clonic convulsions before and after admission to the hospital at noon. The physical examination was essentially negative. Temperature and spinal fluid were normal, and blood pressure was 60/40. Death occurred nine hours after admission. The pathologic findings of a twentyGm thymus, prominence of lymphoid tissue, calcification and ossification of the central portions of the adrenals, with a thinned or absent cortex in places, are almost identical with those of the preceding case, except that in the lymphoid nodules in the various lymphoid

FIG. 2 Case 7

Photomicrograph of adrenal. At the extreme right is thickened fibrous capsule. The diagonal, finely dotted zone running across the right center of the field represents remains of the cortex with scattered leucocytic reaction. The remaining portion to the left of this zone is medulla ($\times 120$)

tissues of this case, there was evidence of toxic injury to cells

CASE 7 The last case is that of B B, male, age eleven whose past history seems interesting in several ways. He had had the usual childhood diseases, always with a tendency to vomit in connection with the acute stages, also bronchopneumonia six years previously and a moderately severe attack of rheumatic fever five years previously. About two years previously he had had a severe illness characterized by vomiting of unknown cause. He was visiting with relatives at the time so the details of this illness are not known. For several weeks prior to the present illness his appetite had been unusually large, but with a violent dislike for carbohydrates. The present illness began two days before

his death with an attack of vomiting without abdominal pain and without fever. This occurred during the night. The next morning the vomiting was more severe and there was generalized abdominal pain. In the middle of the morning he went into collapse.

It was obvious that he was desperately ill, apparently in marked collapse, with poor color, very rapid and thready pulse, and marked listlessness. There seemed to be no important findings in the abdomen and the physical examination was essentially negative except for the signs of collapse. After administration of adrenalin, whiskey, and $\frac{1}{160}$ gr atropine his color improved and his circulation was obviously better. I saw him about three hours later when his condition seemed

FIG 3 Case 7

Another photomicrograph of the adrenal showing in the lower central section a portion of the cortex with numerous scattered leucocytes similar to the diagonal zone in Fig 2. Upper and left portion is medulla. The extreme right upper corner is an island of surviving, relatively normal, cortex ($\times 120$)

much improved and again about eight hours later when he was comfortable, his color and pulse good. Temperature was still normal. He apparently slept fairly well that night but at intervals was somewhat restless. He did not vomit again until the next morning, when he was seen by his physician, Dr. Dewitt Brougham, through whose kindness I am reporting the case. He apparently was fairly comfortable and in good condition until that night, roughly forty-eight hours after the onset, when he fainted as he was being taken to the bathroom. He was seen again by Dr. Brougham who apparently found him in very much the same state of collapse as that in which I had seen

him the preceding day. He was admitted to the hospital at 10 o'clock that night at which time his temperature was 101° . He was extremely restless, completely disoriented, cyanotic, and pulseless. With sedatives he became fairly quiet after admission, although he vomited at times during the night. Fluids were given by vein with some response but he expired eight hours after admission.

Pathologic Findings (M.A. 3538) — Autopsy was performed by the writer two hours after death. Thymus weighed twenty-five Gm. The mesenteric lymph nodes were moderately enlarged. There was slight smooth thickening of the mitral valve leaflets with considerable patchy

FIG 4 Case 7

Photomicrograph of adrenal Higher magnification showing boundary line between cortical zone and medulla. The right three quarters in the section shows degenerating cortex with scattered leukocytes. The zone on the left is medulla. ($\times 500$)

yellowish intimal thickening just above the aortic valve. In the left lateral wall of the left ventricle there was a distinct area of fibrosis about six mm in diameter. Adrenals weighed 2.2 Gm. On section they were firm in consistency, rather grayish in color, and without the usual adrenal markings. The urine in the bladder failed to show acetone or sugar. Aorta seemed distinctly small and thin walled. Thyroid not remarkable.

Microscopic Findings—Area of fibrosis in the myocardium. Necrosis and inflammatory reaction in the centers of the lymphoid nodules of the spleen and lymph nodes. The adrenal sections showed striking absence of normal cortical tissue with diffuse infiltration of this zone with lymphoid and plasma cells and a few mono-

cytes and polymorphonuclears. The medullary tissue seemed larger in amount than is usually seen and extended in places out to the fibrous capsule without any cortical zone between. A few small foci of cells which appeared to be remaining cortical cells were found (Figs. 2, 3, and 4). Sections of the pancreas, pituitary, thyroid, liver, and kidneys did not seem unusual. Brain sections showed considerable edema without inflammatory reaction.

Summary and Comment

The first two infants presented the usual story of sudden death without preceding symptoms and represent the group of cases with which you are all familiar. Pathologic findings described as "status thymicolymphaticus" with small adrenals

were present. The interesting fact was that they were both in the same family, both females, and both died suddenly at about the same age of unknown cause.

Cases 3 and 4 were also in the same family and of about the same age as cases 1 and 2. The noteworthy and unusual fact about case 3 was that it was observed over a period of two months with attacks of syncope of undetermined cause, then died suddenly and the pathologic findings were those of status thymicolymphaticus. This would suggest that the mechanism which causes the sudden deaths of this type may in certain instances operate to cause sudden attacks of obscure collapse with recovery. Case 4, the sister of case 3, at about the same age began to have attacks of the same sort, but still survives.

Cases 5 and 6, ages two and two and a half years, are apparently cases of acute adrenal insufficiency on a basis of old calcified pigmented lesions, probably an old hemorrhage. Otherwise the pathologic findings were those of status thymicolymphaticus. Both had been well since the neonatal period until convulsions and collapse occurred a matter of hours before death. Such old lesions in the adrenals have been given fairly often as incidental findings in routine autopsies with other adequate causes for death. The clinical history of convulsions and sudden collapse in these two cases is especially interesting in connection with the acute crises which may occur in connection with chronic Addison's disease and the therapy of those crises.

An eleven year old boy (case 7), who presented for two days marked collapse, conceivably might have died suddenly at any time, showed at autopsy hyperplasia of thymus and lymphoid tissues and marked atrophy and degeneration of the adrenal cortex. This type of nontuberculous adrenal atrophy has frequently been described in adult cases of Addison's disease, but to my knowledge has not been described in children. Its cause is unknown but it has been compared to the various types of liver degeneration and necrosis of unknown etiology.

These clinical and pathologic observations with regard to acute adrenal insufficiency (either on a functional or anatomic basis, or both), seem interesting to us in the light of recent progress in our knowledge of the adrenals. They have prompted us to undertake a study of electrolyte metabolism particularly that of sodium and potassium in apparently normal and sick children, hoping that it may offer an approach to the so-called thymicolymphatic problem. That work is in progress.

Discussion

Dr. George R. Murphy, *Elmsira*—Let me congratulate Dr. Wyatt on his excellent paper and case studies. I am delighted to see that he hopes to be able to study some of the cases in which he suspects sudden death may occur.

Unfortunately so-called status thymicolymphaticus has been, and still is, the waste basket for cases in which there are no obvious causes of death. Careful research into the history, study of the clinical findings, and complete necropsy will tend to make these diagnoses fewer each year.

It is interesting to note that in New York State, exclusive of New York City, during the past seven years there have been reported a total of cases each year from seventy-one to one hundred seventeen as being caused by either status lymphaticus or thymus gland. Seventy-five per cent of these cases were in children under one year.

A study of the literature on this subject reveals an amazing situation. Status lymphaticus has been given as the cause of sudden death since Plater's case in 1614. Attempts have been made to diagnose this condition during life, and Norris of Bellevue described a definite type in certain males, who were said to have an "angelic" body, whatever that may be!

The association of status lymphaticus and emotional instability has been suggested by many observers, and one of the causes of sudden death ascribed to this condition is that of suicide. In fact, even gunmen who met death by violence were said to have shown evidence of status lymphaticus. This peculiar reasoning which ascribes death by violence to a condition which is not particularly easy to diagnose, and which is based merely upon certain findings at autopsy makes one feel that status thymicolymphaticus has been so impressed on the medical profession, that even when they have an obvious cause of death they are inclined to suggest that the thymus is involved.

In reviewing various charts at our two local hospitals (Arnot-Ogden Memorial and St Joseph's hospitals Clinica) I have frequently found that the resident has signed the death certificate as status thymicolymphaticus in cases when there was an obvious pneumonia meningitis, or congenital heart condition etc., because he was apparently impressed by the supposedly large thymus found at autopsy.

Dr Helen Ingleby of Philadelphia Pa has listed six general causes of sudden death with about fifty subdivisions. These general causes are included in the following groups:

- 1 Circulatory failure
- 2 Cerebral death
- 3 Respiratory death
- 4 Shock
- 5 Neuro-endocrino-humoral death
- 6 Intoxication

One of her subdivisions under the fifth heading is known as reflex inhibition a term much favored by the Germans, and to me about as valuable as the term of status thymicolymphaticus.

Those of us who have been in practice long enough have all seen cases of sudden death and have experienced the terrific emotional strain of trying to explain the situation to the parents of the child. On May 21, 1935, I was called at 8 A.M. by an excited father. I arrived at the house within five minutes to find the child age two months to the day dead. This child had been under my care since two weeks of age had been a full term baby with a normal delivery weighing eight pounds at birth. He was on an evaporated milk formula he had done very well and weighed a little over twelve pounds at time of death. An autopsy was performed and we found a thymus which weighed 39.5 Gm, a patent foramen ovale and a patent ductus arteriosus. There was some mesenteric adenitis and microscopic examination of the pancreas showed very few islands of Langerhans' and in these the cell nuclei stained poorly. I do not know what caused this baby's death one can speculate and that is about all.

In two other cases which were diagnosed as enlarged thymus prior to death one showed a neoplasm of the lungs and the other multiple lung abscesses.

I have seen also two cases which were given six to ten doses of x-ray soon after birth. They failed to grow in weight or length and at time of death weighed less than at birth. The ages at death were six and eight months respectively.

There is no question that one sees certain types of cases in which irradiation of the thymus does seem to aid the clinical symptoms. Possibly

these symptoms would have disappeared if a period of watchful waiting ensued. I do know that I find it much less necessary to request irradiation now than I did earlier in my practice. If it is necessary I request not more than two exposures with an interval of two weeks.

A Graeme Mitchell says "The theory of suprarenal deficiency has much in its favor and is supported by certain physiological and pharmacological facts. Suprarenal insufficiency seems to be a possible explanation of certain cases of sudden death which can be accounted for in no other way. What this has to do with the thymus is another matter although there may be an associated thymic and lymphoid hyperplasia and it is interesting that in suprarenalectomized animals there follows a hypertrophy of the thymus according to Marjoe et al."

J F Casley presents a personal case of a child eight months old who died suddenly and on whom a diagnosis at necropsy of status thymicolymphaticus was made. Twenty-four hours later a blood culture grew meningococci.

Conclusion

1 There is little sound basis for the association of an enlarged thymus and sudden death.

2 Diagnosis of enlarged thymus is to be made by exclusion plus careful x-ray studies in both lateral and A-P planes and in both phases of respiration.

3 It probably does no harm to give one or at most two x-ray treatments especially if the parents have been frightened by a possible accident.

4 It is sometimes necessary to use the diagnosis of status lymphaticus when trying to console parents. Let us be most careful to be honest with ourselves, however, and admit that we do not know the cause of death in a given case.

5 All cases of sudden death should automatically be investigated by careful study of the history, examination of the patient's environment and a thorough complete autopsy.

713 E GENESSEE ST

Dr Reginald A. Higgins, Port Chester—
The subject of "thymic death" is one which most interest all pediatricians, if for no other reason than it is ever being brought forcibly to our attention by an apprehensive and only partly informed laity.

Unfortunately even our own group is divided into many camps, both as to the true pathogenesis and also the proper treatment of the state called status thymicolymphaticus.

Back in 1614, Felix Plater described the presence of a large thymus gland in a case of sudden death, and in 1830, Kopp first attributed sudden death to the pressure of an enlarged thymus.

Many workers have described the relative hypoplasia of the adrenals, which accompanies the hyperplasia of the lymphatic system in these cases.

In 1914, Cannon demonstrated the relationship of diminished epinephrin production to the blood sugar level, and the consequent inability of muscles to withstand fatigue.

In 1917, Symmers first suggested an allergic basis for the symptoms. He thought that the body might be sensitized to the nucleoproteins of the disintegrating lymph follicles.

In 1928, Zeek reported two "thymic deaths" as due to rupture of hypoplastic cerebral arteries.

In 1932, Boyd reported an exhaustive study of the size and weight of the thymus, with the opinion that there was a great variation normally and that the size always decreased rapidly before death, in the presence of any illness of more than twenty-four hours duration.

Rowntree reports no increased susceptibility to shock in rats receiving continuous injection of thymic extracts, although these rats showed marked structural changes.

Greenthal reports no thymic deaths in 2,000 surgical anesthetics where all cases showing any increased thymic shadows were treated by x-ray before operation.

On the other hand, a study of 31,163 tonsillectomies at the New York Eye and Ear Infirmary, showed only three deaths which could be classified as "thymic deaths."

Nesbit suggests a diminished parathyroid function in these cases, with a consequent fall in serum calcium levels. He thinks radiation may benefit through increasing the calcium level.

The above are only a few of the thousands of conflicting observations upon this subject in our current literature. Time does not permit a fuller review.

At present I am more impressed by the work which suggests an allergic state in these cases.

Tumpeier (1934) found enlarged thymic shadows in 158 of 183 so-called allergic children.

Waldbott studied thirty children who had previously been treated by radiation for enlarged thymic shadows. He found twenty-five of these children to be allergic as indicated by skin testing.

He also reported evidence of an allergic shock reaction from nonprotein substances administered otherwise than by injection. These included reactions to ether and to local anesthetics.

Finally he compared the pathological findings in so-called thymic deaths, sudden deaths from asthma, and deaths from anaphylactic shock. The three groups showed the same characteristics with regard to the lymphoid tissues and the adrenals. He felt, however, that the primary pathological change was in the lungs. These showed edema, petechial hemorrhages, capillary dilatation and eosinophilia, with some organization, or even early necrosis in cases which lived long enough. He felt that the edema was the primary pathology with death resulting from asphyxia.

In Dr. Wyatt's cases, the familial tendency, the repeated mild attacks before death, the relative lack of response to radiation, the temporary benefit of adrenalin, the resemblance of many of the symptoms to those of anaphylactic shock, and the findings of edema of the lung tissue, all suggest an allergic shock reaction.

It appears to me that the states of status thymicolymphaticus, allergy, hypoadrenal function, may all be different manifestations of a common basic cellular pathology, the cause of which is still unknown.

FORTY DOCTORS ON FAIR STAFF

When the World's Fair opens next April a staff of forty physicians and seventy nurses will be on hand to administer first aid, Dr. Joseph C. Hoguet, director of the medical department of the World's Fair, discloses.

A special x-ray mounted on a truck will be ready for any emergency. Equipped with a darkroom, the automobile will answer calls from any of the eight first-aid stations.

In addition, the medical unit is planning to have a speed boat, fully equipped with hospital and surgical instruments, to be used in such emergencies as drowning or gas asphyxiation. Several obstetricians will be on the staff to be ready for the dozen or more births expected during the six months' period.

Besides the visitors, the medical staff will have to take care of a permanent body of about 50,000 fair employees.

Mt. Sinai Hospital offers an eight-week's advanced course in neuro-ophthalmology from February 6 to March 31. Details on application.

Nurse "No change yet, doctor."—*Firfax*

"GET THEM BACK"—

Surgical Lessons from the War

CONDUCT W. CUTLER, JR., M. D., The Roosevelt Hospital New York City

TWENTY years ago the war to end war came to its abrupt conclusion. No one could have been happier to see it finished than the surgeons and nurses whose lives, for two years, had been lived in an atmosphere of human misery which they had tried—how often ineffectively—to alleviate. War to them could mean but one thing—human wreckage. Peace brought a cessation of injury, but for many long months the battle for life and health still went on in the hospital wards. Even today, it is still going on for some of the wounded—twenty years after.

How often we have heard it, in these intervening years, that familiar exclamation: "What a wonderful experience it must have been for you to be a doctor in the war!" We have learned to agree pleasantly with this observation. For though we know all too well, we cannot convey to one who has not shared it what that experience really meant. Professionally speaking, our experience was dearly bought, and hardly worth the price we and our patients paid for it.

Perhaps it may be well to try to evaluate that experience, from the professional aspect solely, looking back through the years of civilian practice with an appraising eye. What did we learn in those bitter days? How much have we kept and valued for the better application of our art to the problem of healing in a community at peace?

From the point of view of one who was ordered as a Casual Officer to fill a place in the Roosevelt Mackey Unit—Base Hospital 15—, who was side tracked to the front where the need was greater and who served with a combat division, in many capacities, for some months before reaching the original destination, it is possible to give a brief cross section

of surgical service to the wounded from its crude beginnings to its termination.

It is a gray, wet dawn in the trenches of the front line. The flame and crash of the harrage is spreading forward across the enemy wire. Poised and ready, the men are waiting for the whistle that will send them over the top. The medical officer is there. His men know what they will have to do. He knows the objectives of the attack in his sector, and something of the terrain, the lay of the trenches, roads, and paths. Perhaps at the jumping-off place, perhaps somewhere out in the fields or woods ahead, still in enemy hands, he must find a spot accessible to the wounded, yet providing them some shelter. A dugout, the cellar of a ruined house, the lee of an embankment, perhaps only a shell crater must serve his purpose. There, as the attack sweeps forward, his first aid station is set up and marked. And now the wreckage of the attack drifts back to him. The wounded come, some walking singly, some in pairs, helping one another, some carried on the backs of comrades or by prisoners, a few on stretchers manned by sanitary corps men or by bandsmen whose duty now is quite different from that on parade.

Faced with every type of injury that gas, shrapnel, high-explosive shell, rifle bullet, machine gun bullet, rifle butt, and bayonet can produce, what can the surgeon and his handful of men accomplish for the aid of the wounded? Very little to be sure, especially if the casualties be heavy and the work is hampered by shelling, gas, mud, and rain. But he can and must get them back, back to

relative safety and to better care than he can give now. A crude dressing here, an improvised splint there, a tourniquet for this one, morphine for that, tetanus antitoxin if it holds out. Then a tag, hastily scrawled and attached to a button. But always—get them back. Some can still walk or be helped to a communication trench or road, some must be carried. Some must stay where they are, sheltered as best they can be, and eased when opportunity affords. Some of them will not need to be moved. The burial squad will take care of them later.

Back at the road, better shelter may be found, possibly another dressing station, but here, still, the slogan is "Get them back." A dressing renewed, a tourniquet eased, antitoxin or morphine administered, a splint readjusted, perhaps the luxury of a cigarette until the ambulance can get through.

But the ambulance company, under its surgeon commander, has but one purpose and one idea—get them back. Over shell torn roads, often hardly passable, after dark, usually, and without lights, the faithful creaking Fords jounce and sway and rattle, carrying their loads of wounded. Some sit on the tail-board, holding on precariously, others lie on the floor or on the stretchers in their racks against the sides. Speed is the watchword, not comfort, for there are many to evacuate, and all night long the drivers must slam their cars back and forth over these roads with troops and guns and ammunition moving up along them, giving them no right of way. The wounded must get back.

Some kilometers back, the ambulances drop their loads. Perhaps it is at a divisional field hospital housed in huts, or Bessoneau tents, or possibly in an abandoned château. Such a hospital moves with its division, locating where it can. Its trucks stand somewhere nearby. It may be here to day and gone tomorrow, but now it is prepared for the business in hand. Probably here there will be cots, certainly blankets, a hot drink for those who may be given it, a respite of rest. Here, too, there are

surgeons, an improvised operating room. One or more of the mobile operating units may give it additional capacity for the care of the wounded.

Now one can begin to consider a little such problems as the combating of shock, the replenishment of depleted body fluids, the nature of the wounds and their demand for immediate surgical intervention. Here, dressings and clothing can be removed, a little cleaning up done, and wounds appraised. The less seriously wounded, their pain eased, may sleep a little in their exhaustion.

But, as the wounded keep pouring in from the hurrying ambulances, there is not much time for refinements of care. The operating rooms, lit by flaring lamps, will run all night, perhaps all day. Débridement of compound fractures and the application of Thomas splints. Amputation sometimes. Exploration of abdominal wounds and repair of visceral injuries. Exploration of head wounds and the elevation of bone fragments and extraction of metal. Closure of chest wounds. Débridement of the worst soft part wounds. These are the operating room activities, repeated over and over again. Always more wounded await their turn, driving the surgeons on hour after hour. And meanwhile, among the cots, there are dressings and still more dressings to be done. There may be nurses here, probably not.

Or, instead of at a divisional field hospital, the ambulances may have discharged their loads at an evacuation hospital, located more or less permanently at some convenient crossroads, not too far from the front. Here, because of its greater permanence of locale, housed in a cluster of wooden buildings designed and erected for the purpose, the facilities for handling a peak load of wounded may be somewhat more elaborate than in the wandering field hospital. But the nature of the work is much the same, and here the wounded may be dressed and operated upon by the operating teams much as in the field hospital.

In either hospital of this type, as the wounded pour in, each bringing its

special problem of treatment, driving the staff to the limit of their physical endurance, we learn anew, and of necessity, the lessons of serious acute traumatic surgery. We learn the need of combating hemorrhage and shock, and come to appreciate, as never before, the values of infusions and of transfusions—though the facilities for the latter are much less than we could wish under these circumstances. We learn that injured and exhausted men will survive much better the ordeal of operation, even though their wounds seem urgent, if given a few hours of rest and relief from pain beforehand. We learn the need of the radical surgical cleansing of wounds of all dirt, clothing, metal, bone fragments, and devitalized tissue, even though the débridement may be mutilating. Life itself may hang upon an apparent ruthlessness, and may be lost for the lack of it. We learn the necessity of early closure of chest wounds, of early exploration and repair within the penetrated abdomen, of the dreadful urgency of spreading gas gangrene. We learn the destructive effect of transportation without adequate splinting of compound fractures. And, guided by these stern lessons, our help to the wounded becomes by degrees, more intelligent and more effective. We of Base 15 know all this well, for our own unit served as an evacuation hospital during the offensive in the Argonne.

But the journey of the wounded is not yet done. A field hospital must maintain its mobility and cannot harbor patients for long. An evacuation hospital must always make room for fresh influx of wounded and must not remain filled. Its very name indicates its purpose—to get them back. So day by day, for some of the wounded, the weary pilgrimage to the rear goes on. Sometimes by ambulance, some times by hospital train, they are moved back to the base hospitals, their immediate problems having been dealt with as well as could be done in the feverish haste of the advance zone. At last, they will be away from the unceas-

ing thunder of the front, from the menace of gas and of air raids. But the stream that flows back has thinned out a little. The slightly wounded have returned to their regiments or have been sent to convalescent camps. Sepsis, pneumonia, hemorrhage, peritonitis, too, have taken their toll all along the way. And yet the receiving base hospitals are filled and stretcher bearers, surgeons, and nurses must work night and day when the trains come in.

But here, at the base hospital, for all the overwork, there is still time for nursing care to bring comfort and ease. Problems of treatment may be reviewed, laboratory and x-ray work brought to the patients aid, fractures reset and arranged with traction and suspension, overlooked metal fragments removed, repair of tissue damage begun and the slow business of healing and recuperation promoted by careful dressings and medical care. We learn what may be accomplished in fractures by the proper application of the principles of suspension and skeletal traction, as we spend long hours in the wards forested with Balkan frames. We learn how sloughs will separate and wounds grow clean, healthy, and relatively free of bacteria under the conscientious application of the Carrel-Dakin treatment, and can even make secondary closures of many of them and see them completely heal. We learn by observation, and to our amazement, that long neglected wounds, badly contaminated and swarming with maggots will appear more healthy and heal more kindly than similar wounds not thus infested. We even attempt some plastic surgery to restore to a degree of usefulness extremities crippled by injury, and to bring some semblance of order out of the chaos of damaged features.

When all that we can do has been done, our wounded leave us, some to return eagerly to duty, others regretfully to continue their long journey home, incapacitated for further fighting. For these, the war is over. For many, their days of active life are over too. But, as the convalescents leave, other trainloads

arrive to take their places, and the work goes on and on. Such are the experiences of war-time surgery.

What did we bring back from all of this? Not much, it must be admitted, that would add greatly to our skill and knowledge in civil practice, a good deal, perhaps, in familiarity with the problems of traumatic surgery. Into our interrupted practices and to our hospitals, we brought back from war days the principles of the management of patients in shock, of the débridement of lacerated, contaminated wounds, of the application of the Carrel-Dakin treatment, of the maggot treatment of suppurating wounds and osteomyelitis, of the uses of suspension and skeletal traction in the management of fractures, of the rudiments of plastic surgery. With these and other lessons learned we have been better equipped to serve the rarer injuries of civil practice that require them. Some of the things we were taught in the hard school of war experience have been superseded by better

methods in the twenty intervening years, some have gone on to development and improvement, some are falling into disuse, but they served our need in their time. The science of surgery must advance, but one thing our experience has taught us, if no other—that warfare is not the best way to advance it.

We have forgotten, happily perhaps, much that happened twenty years ago, but one bright memory remains with all of us who spent our days and nights in work with the wounded. It is the recollection of the bravery and fortitude and spirit of the American citizen soldier, shown not alone on the field of action, but in the long tedious battle for life and health fought out hour by hour and day after day through the ordeals of injuries, operations, and dressings. Often, we rejoiced in his victorious recovery, sometimes we mourned his defeat, but whether winning or losing his fight, his courage never failed. This, at least, we cannot forget.

HALF THE "DIABETICS" CALLED "JUST FATTIES"

A press dispatch from Winnipeg reports that Professor L. H. Newburgh, of the University of Michigan, told the Manitoba Medical Association's annual convention that fifty per cent of the persons diagnosed as suffering from diabetes are "just gluttons, only they won't admit it."

"According to life insurance statistics," he continued, "there are 2,000,000 middle-aged obese individuals in the United States with diabetic symptoms."

"They're not diabetics at all, they're just fatties," he added.

He recommended a milk, vegetable, and fruit diet, and declared the "meat eating fallacy" started in Germany years ago, when a German concluded the way to be strong and healthy was to eat meat.

"The result was the Germans thought they could lick the world if they built their diet around meat, and that idea was absorbed by other countries."

"THROW AWAY" MAIL

In addition to "throw away" journals there is much "throw away" mail that comes to a physician's or dentist's desk, remarks the *American Journal of Medical Jurisprudence*. "Throw away" is what this mail deserves. Drugs, books, pills, equipment, shirts, socks, and more pills and ointment, sales copy, as well as samples, clutter the professional man's mail. Rightly, all this junk reaches its proper destiny, the waste basket, unopened. Secretaries rightly

direct such consignment and conserve the time of their employers, as well as relieving the doctor of this modern mail annoyance.

Some communities have ordinances prohibiting doorstep distributing of circulars and samples. Hail to the federal legislator who obtains the passage of a law prohibiting promiscuous mail circularization until a permit is obtained and control is exercised over this nuisance.

The Administration of Arsphenamine Preparation of Patient and Drug, Technic of Injection

Of all antisyphilitic remedies so far tried old arsphenamine is generally acknowledged by syphilologists to be the most active of those tolerated in therapeutic doses. Its universal adoption has been delayed chiefly by the lack of a safe and simple technic of administration. In the early experimental period it was given subcutaneously and intramuscularly, but on account of the severe pain and local necrosis which it caused, these methods were soon abandoned in favor of the intravenous route. Until recently the

use of old arsphenamine has been practically limited to the larger clinics, because of technical difficulties involved in its preparation and administration. The original acid solution is highly toxic and must be alkalinized before injection. This alkalinized solution is unstable and so far no satisfactory method has been devised for preparing it in advance for commercial distribution. Furthermore, the high dilutions generally advocated necessitate the setting up of a gravity apparatus. These combined difficulties have led the general practitioner to fall back on preparations which are easier to administer, such as neoarsphenamine

despite the fact that this, like other substitutes, is relatively inactive in small doses, and too toxic in doses high enough to be therapeutically active

A simplified technic has now been devised whereby the principal drawbacks to the administration of old arsphenamine have been overcome. The tedious and uncertain method formerly in use, of alkalizing the acid arsphenamine solution with sodium hydroxide solution prepared in bulk and added drop by drop, has been replaced by the introduction of arsphenamine in ampules of different sizes, each accompanied by an ampule of sodium hydroxide solution of the exact strength required to alkalize the corresponding dose of arsphenamine. In place of the old cumbersome gravity apparatus, the syringe may be used to administer the drug provided certain simple precautions are observed.

A three-year trial of this method at the Vanderbilt Clinic, in the treatment of all forms of syphilis including syphilis in infants and children, has proved it to be almost as simple as the technic used in the administration of neoarsphenamine or silver arsphenamine. It is particularly useful in private practice, where ordinarily only a few cases—sometimes not more than one or two—are treated at a time. It is believed that this method will make available to the general practitioner a rational treatment plan hitherto practicable only in the larger clinics and in the office of the specialist. For details of the method, see section entitled "Preparation of Drug and Technic of Injection."

Instructions for Patient—Give the patient the following written instructions in advance

- 1 Take a mild cathartic the night before the injection (cascara or milk of magnesia)
- 2 Take no food for four hours before the injection, except a cup of tea or coffee or a glass of milk, and a slice of dry toast
- 3 Take no food for five hours after the injection, then a cup of tea or

coffee or a glass of milk, with dry toast or saltine crackers

- 4 Rest for fifteen to thirty minutes after each injection

Preparation of Drug—

- 1 Pour sterile distilled water at room temperature into sterile Erlenmeyer flask, 5 to 10 cc for each decigram of the drug. Children tolerate easily down to 5 cc per decigram
- 2 Use old arsphenamine marketed in ampules of different sizes, each accompanied by an ampule of sodium hydroxide solution of the exact strength required to alkalize the corresponding dose of arsphenamine *
- 3 Immerse ampules of arsphenamine in alcohol to detect cracks. Do not use if the ampule is cracked, or if the powder is off-color (it should be pale yellow or lemon-colored)
- 4 Dissolve the arsphenamine by sprinkling the powder on surface of water. Avoid lumps, as they will not dissolve easily
- 5 Allow the solution to clear, be sure there are no gelatinous masses
- 6 Alkalize the solution by adding the correct amount of sodium hydroxide from ampule packed with the corresponding dose of arsphenamine.
- 7 Rotate the flask gently, allow to stand until flocculation has cleared—at least 15 minutes, up to two hours at room temperature covered will do no harm
- 8 Test for alkalinity with litmus paper, if red litmus turns blue, the solution is ready to inject

Equipment for Intravenous Injection—Use a 20- to 23-gage Fordyce needle with corrugated wing, and an all-glass syringe. The needle may be attached to the syringe, or may be entered first into vein and the syringe then attached. It is better to use an adapter, even when not strictly necessary, as the adapter will protect the nozzle of the syringe against

* If not obtainable locally, they may be ordered from Dermatological Research Laboratories, 1720 Lombard Street, Philadelphia, Pa

chipping or breaking. If a syringe of more than 20 cc capacity is used, or if the syringe and the needle do not fit perfectly an adapter will be necessary. Needles should be sharpened smooth and both needle and syringe sterilized by boiling. After filling syringe with arsphenamine solution, be sure to expel air from syringe, in order to avoid danger of embolism.

Figure 1. Technic of intravenous injection: tourniquet applied; operator's left hand steady; patient's forearm extended; right hand holding needle and syringe ready to enter vein.

Preparation of Patient—With the patient lying down, expose his arm, fully extended. Tie a rubber tourniquet well above the elbow, making it tight enough to stop the venous circulation but not so tight as to obstruct the arterial flow. Point the ends of the tourniquet up the arm, out of the field of operation. The tourniquet should be removed just before the injection is started. Any vein in the anterior cubital region may be used for the injection. To make the veins stand out a hot towel may be applied, or the vein slapped, or the patient is told to clench and open his fist several times. Clean the skin over the vein with cotton moistened in alcohol.

Technic of Intravenous Injection—With the left hand steadying the patient's forearm, and with the right hand holding the needle in line with the vein and nearly parallel to the surface, dip the point slightly (bevel edge up), thrust the needle quickly through the skin and venous

wall, and then straighten and advance it 1 to 2 cm within the lumen of the vessel, in the direction of the venous flow. One can usually tell when the needle is in the vein by the flow of blood from the needle, or, if attached to a syringe, by the appearance of blood therein. If a small gauge needle and small syringe are used, it may be necessary to aspirate by drawing back slightly on the piston before blood will appear. With a needle of larger caliber, blood usually flows out spontaneously.

If the operator distrusts his technic and wishes to take additional precautions against paravenous infiltration of the arsphenamine, he may have at hand an extra syringe containing warm sterile water or physiologic saline, from which he injects a few cc after the needle is in place. If infiltration occurs, no harm is done, and another site can be tried, if no signs of infiltration appear, the syringe is replaced by another containing the ars-

Figure 2. Technic of intravenous injection: tourniquet off; needle in vein held steady by corrugated wing; slight show of blood in syringe; injection proceeding slowly.

phenamine solution and replaced in the needle. During these manipulations, care must be taken not to displace the needle in the vein.

Inject the solution slowly—not more than 10 cc. and preferably not more than 5 cc per minute. Watch the patient for flushing of the face and other signs of unfavorable reaction. When the injection

has been completed and the needle withdrawn, have the patient press down over the site of injection for several minutes with a cotton or gauze swab dipped in alcohol, and then cover it with adhesive tape. It is better to use alternate arms for subsequent injections. If patient complains of pain or discomfort at point of the needle or up the course of the vein after the arsphenamine injection is begun, remove the needle, even if no local swelling or infiltration can be detected, and reinsert it in another vein. If an infiltration is present, or if there is pain up the arm, massage the area at and around the puncture wound deeply and thoroughly for five or ten minutes, and then apply hot compresses to the arm for about half an hour. This treatment will usually prevent necrosis and will greatly minimize the subsequent discomfort and local redness. The hot compresses may be continued four or five times a day if necessary, and if local redness and swelling do take place, a thick dressing of ichthyol ointment may be applied between hot applications. Thorough massage at the time the infiltration occurs is the best remedy of all.

If the arm veins are difficult to enter, any other vein (including varicosities) may be used. In difficult cases, or in areas sensitive to puncture, it is well to spray the skin with ethyl chlorid to deaden the superficial nerve endings, before attempting entry. In treating children whose arm veins are difficult to enter, one may use ankle, jugular, or scalp veins. In the latter case, place a rubber tourniquet around the base of the skull to make the veins stand out.

Reactions to Arsphenamine—IMMEDIATE AND EARLY (SLIGHTLY DELAYED) REACTIONS

1 Nitritoid crisis and mild vasomotor and anaphylactoid reactions. These are due chiefly to too rapid administration of the drug. They occur during or immediately after the injection.

2 General malaise, headache, nausea, vomiting, and diarrhea. These reactions are usually due to dietary indiscretions of the patient. When accompanied by chills and fever, they may be the "tubing reac-

tion" or may be due to contamination from impurities in the water or to faulty technic. They occur within twenty-four hours after the injection.

3 Mild and transitory skin eruptions. Urticaria, scarlatiniform, and morbilliform rashes. Some rashes are possibly due to the reactivation of latent infections by the drug. They usually occur within twenty-four to forty-eight hours after the injection. Urticaria may occur during the injection, with or without other symptoms.

4 Herxheimer's reaction. A flare-up of syphilitic lesions following the first injection of an arsphenamine, especially serious in cardiovascular syphilis. Occasionally, meningeal symptoms and cranial nerve palsies occur in patients with early subthreshold involvement of the nervous system.

5 Pain in the chest and back, cough, pallor, collapse, and cardiac failure. These are due to the injection of a concentrated solution of unneutralized (acid) arsphenamine. "Doctor or attendant mistook it for neoarsphenamine."

DELAYED REACTIONS

1 Skin (exfoliative dermatitis). Generalized, vesicular, exudative dermatitis, frequently associated with grave constitutional symptoms, and characterized by scaling and extensive exfoliation in the later stages. It is usually preceded and accompanied by intense itching. It is caused by idiosyncrasy to arsenic compounds and undue retention of arsenic in the system. Its occurrence bears no relation to the number of injections.

2 Liver (jaundice). Varies from mild hepatitis resembling catarrhal jaundice to acute yellow atrophy, the latter usually fatal. It is probably due to retention of arsenic, superimposed on damage by syphilis and/or intercurrent infection. It may occur as late as several months after the last arsphenamine injection.

3 Kidney (nephritis). The usual clinical manifestations, with albuminuria and, occasionally, hematuria. It is more marked when mercury or bismuth is used concurrently with arsphenamine. It is rarely caused by arsphenamine alone, but

when it is, it is far more likely to occur as a complication of dermatitis, jaundice, or neuritis. It should not be confused with syphilitic nephritis, which clears miraculously under specific treatment.

4 **Nervous system.** Peripheral neuritis, ranging from mild forms (numbness, tingling, paresthesias) to severe forms followed by muscular atrophy, hemorrhagic encephalitis, which is comparatively rare in the United States and is more likely to occur after neoarsphenamine or sulfarsphenamine in high dosage.

5 **Blood dyscrasias.** Aplastic anemia, agranulocytic angina, usually with stomatitis of varying degrees, and purpura hemorrhagica. These are comparatively rare, but serious and sometimes fatal.

Prevention of Reactions to Arsphenamine.—Most reactions are preventable, being due to faulty technique, inadequate preparation of the patient, too high dosage, too abrupt initiation of arsphenamine therapy especially in the later stages of syphilis, or to neglect of warning symptoms.

1 **Technic.** Give careful attention to details of preparation of drug and apparatus, avoid paravenous infiltration, inject solutions *slowly*, and in adequate dilution.

2 **Preparation of patient.** If possible, give written or printed instructions in advance, as outlined on page 146 and inquire before injection whether instructions have been followed. In case the patient is known to be a reactor, inquire for special symptoms following the last injection. If the patient was previously treated elsewhere, inquire carefully for any history of reactions to treatment, if possible get the record from physician or clinic where the patient was last treated for syphilis.

3 **Dosage.** Do not attempt to sterilize the patient with a single dose of arsphenamine. Begin the course with the minimum dose and increase gradually to the maximum. If a reaction occurs, reduce the next dose slightly. If the patient lapses before the course is completed, start again on reduced dosage when the course is resumed, and increase as before.

4 **Age of patient and stage of disease.** Do not give arsphenamine to persons over fifty years of age unless the clinical symptoms require it and the general physical condition permits it. In these and in all cases of late syphilis in which arsphenamine is indicated, give preliminary injections of mercury or bismuth before beginning the arsphenamine course in order to avoid therapeutic shock to vital structures.

5 **Observe special precautions in treating pregnant women, and note dosage for infants and children** (see "Treatment Schedule," under these headings). See also *Modifications of Routine Treatment for Special Types of Cases*.

6 **Heed warning symptoms** (a) **Nitritoid Crisis.** On appearance of early symptoms (flushing of face, suffusion of eyes, slightly labored breathing), stop the flow of arsphenamine and wait for the symptoms to subside. Resume injection after five minutes if the symptoms have subsided, and give still more slowly until the injection is completed. A confirmed reactor should be given 10 cc. of calcium intravenously just before the syringe is attached for the arsphenamine injection, or else adrenalin (10 minims) subcutaneously, or ephedrine (1 cc.) intramuscularly 10-15 minutes before the arsphenamine injection. Smelling salts are sometimes effective. It is well to check the blood pressure before giving adrenalin to obese patients.

(h) **Skin.** Inquire of the patient before each injection whether he had a skin rash or any other untoward effects following the previous injection. If any of the mild skin eruptions have occurred—urticarial, scarlatiniform, morbilliform, or slightly dry, red, scaly patches—skip one injection and then resume treatment on slightly reduced dosage, giving sodium thiosulfate between arsphenamine injections. These rashes are not a contraindication to further treatment, but call for caution. Any suggestion of a moist, swollen exudative dermatitis indicates a true idiosyncrasy to arsphenamine and calls for immediate cessation of treatment.

(c) **Liver.** Jaundice is usually preceded

by anorexia, nausea and vomiting. Palpate for enlarged liver and take blood for bile index (above 15 is suspicious). Look for jaundiced urine when urine is shaken in test tube the foam is icteric. In colored patients especially, watch for icteric sclerae. Discontinue arsphenamine temporarily in the presence of other symptoms without waiting for clinical jaundice to appear.

(d) Kidney. Make frequent urinalyses (every one or two weeks). If a heavy trace of albumin is found, stop all treatment and give sodium thiosulfate. Use mercury and bismuth preparations with caution in patients with a history of renal symptoms.

(e) Nervous system. Moderate dosage, alternating of arsphenamine with bismuth or mercury courses, and avoidance of neoarsphenamine and sulfarsphenamine will avert a majority of accidents to the nervous system. If minor symptoms appear, discontinue arsphenamine temporarily and give mercury or bismuth, with iodides. Do not begin arsphenamine without preliminary injections of mercury or bismuth if there is any reason to suspect early involvement of the nervous system, in order to avoid Herxheimer's reaction.

(f) Blood dyscrasias. Take blood counts at frequent intervals (a complete blood count once a month). Eliminate foci of infection, especially in the mouth. Note any history of hemorrhagic diathesis in the patient or his family. A consistently falling leukocyte count, even if still within the lower limits of "normal" should be looked upon with suspicion, especially if there is a disproportionate fall in the number of polymorphonuclear cells. A total white count of 3,000 or less, with both absolute and relative decrease in the granular leukocytes, calls for prompt cessation of all treatment. Endeavor to eliminate arsenic by injections of calcium or sodium thiosulfate, force fluids, and proceed as in heavy metal intoxication. This technic is designed to prevent agranulocytosis. The red cell count is rarely if ever affected enough to require cessation of arsphenamine treatment.

More often than not, arsphenamine, if given in small to moderate doses, will stimulate erythrocyte production and hemoglobin.

Treatment of Reactions to Arsphenamine—(a) Nitritoid crisis. For a true nitritoid reaction subcutaneous injection of adrenalin (10 minims) is usually recommended, but I have found the best remedy for the milder reactions to consist in lowering the patient's head and having him alternately take repeated long breaths and hold his breath. Smelling salts also help. If the reaction is severe, and the patient unconscious and pulseless, give adrenalin intravenously (5 to 10 minims) and keep the patient warm with a blanket and hot-water bottle, as in treatment of shock.

(b) Exfoliative dermatitis. At the first signs of an eruption of the exudative type, stop all treatment and aid elimination of arsenic by giving calcium or sodium thiosulfate, both intravenously (daily injections) and by mouth. Have the patient rest in bed, force fluids, and give a saline laxative daily. For local treatment in the exudative stage, dust cornstarch powder over the skin. When exfoliation begins, apply boric acid ointment or some other oily preparation. Continuous cornstarch baths may be given, or the patient may take a bath every few days. If the patient shows signs of dehydration, glucose injections may be given, either intravenously or by hypodermoclysis. A patient who has once had a true exfoliative dermatitis is rarely able to tolerate further arsphenamine treatment, but it is permissible to try, after an interval of six months or more, giving 0.05 Gm of a different arsphenamine preparation (silver arsphenamine is usually well tolerated). This is a more reliable guide to further treatment than either the patch or the intradermal skin tests.

(c) Jaundice. Stop all treatment and put the patient on a fat-free diet, giving especially fruits and sour foods (sauerkraut, buttermilk). Hasten the elimination of arsenic by the methods suggested for dermatitis. Do not resume arsphen-

amine for at least six months after the jaundice has cleared, and then only in small doses at weekly intervals. Heavy metals and the iodides may be given after the jaundice has cleared and until arsphenamine is begun. The bile index should be taken weekly, on both blood and urine, during arsphenamine courses, in order to prevent a recurrence of the hepatitis.

(d) Nephritis. Stop all treatment and give calcium or sodium thiosulfate.

(e) Neuritis. Stop all treatment. Use massage, hot baths, and baking with electric heaters. Aid the elimination of arsenic as in dermatitis or jaundice.

(f) Blood dyscrasias. No cure is known for conditions resulting from the serious damage to the blood forming apparatus caused by arsphenamine. The best treatment is prevention. See measures described under this heading.

Silver Arsphenamine

Occasionally it becomes necessary to replace old arsphenamine with a substitute, either because the patient has shown himself intolerant to old arsphenamine, or because the Wassermann proves unusually resistant and a drug-fastness is suspected. In such cases I have found silver arsphenamine to be the drug of choice.

Silver arsphenamine is marketed in the form of a dark brown powder, freely soluble in water and alkaline in reaction. It contains approximately 19 per cent arsenic and 12 to 14 per cent silver. It is administered intravenously, usually by syringe, but may be given by gravity.

Preparation of Drug and Technic of Injection —

- 1 Break the ampule in the usual way and dissolve the powder in sterile distilled water at room temperature, 10 cc. to 1 decigram of the drug (children tolerate down to 5 cc.)
- 2 Observe the same precautions as in the preparation of old arsphen

amine, except that alkalization is omitted. Sprinkle (do not dump) the powder on the surface of the water, and allow the solution to clear. The flask may be rotated gently to hasten solution, but do not shake.

- 3 The solution should be used within 20 minutes, as it deteriorates on exposure to carbon dioxide.
- 4 Do not inject unless the solution is clear, like black coffee.

Silver arsphenamine has one disadvantage, in that the dark color of the solution makes it difficult to distinguish the presence of blood when aspirated into the syringe. There are several ways in which the operator may verify the position of the needle in the vein and avoid a paravenous infiltration.

- (a) He may perform the venipuncture before attaching the syringe.
- (b) He may puncture with the syringe attached, and if difficulty is encountered, detach the syringe and allow the blood to flow out from the needle.
- (c) He may have at hand an extra syringe containing a solution of physiologic saline into which he aspirates for blood, as soon as blood is obtained, substitute the syringe containing the silver arsphenamine solution to be injected.
- (d) He may puncture with attached syringe containing a few cc. of physiologic saline, aspirate for blood into this, then detach, fill same syringe with silver arsphenamine solution, and replace in needle.

Reactions to Silver Arsphenamine — We have found reactions after silver arsphenamine to be less numerous and less severe than after either old or neoarsphenamine. Argynia sometimes develops, however, especially in elderly patients if the drug is continued over long periods. Hence the total dosage should not exceed eight grams.

DOSAGE SCHEDULE FOR SILVER ARSPHENAMINE

| DOSE | FOR PREFERRED OR '3-2" PLAN | | FOR ALTERNATE OR 2-1" PLAN | |
|---------------------|--------------------------------|------------------------|-------------------------------|------------------------|
| | Dosage for Men | Dosage for Women | Dosage for Men | Dosage for Women |
| 1st | 0 15 Gm. | 0 1 Gm. | 0 15 Gm. | 0 1 Gm. |
| 2nd | 0 15 Gm. | 0 1 Gm. | 0 2 Gm. | 0 15 Gm. |
| 3rd | 0 2 Gm. | 0 15 Gm. | 0 25 Gm. | 0 15 Gm. |
| 4th | 0 25 Gm. | 0 2 Gm. | 0 25 Gm. | 0 2 Gm. |
| 5th | 0 25 Gm. | 0 2 Gm. | 0 3 Gm. | 0 2 Gm. |
| 6th | 0 25 Gm. | 0 2 Gm. | 0 3 Gm. | 0 25 Gm. |
| 7th | 0 3 Gm. | 0 25 Gm. | 0 3 Gm. | 0 25 Gm. |
| 8th | 0 3 Gm. | 0 25 Gm. | 0 3 Gm. | 0 25 Gm. |
| 9th | 0 3 Gm. | 0 25 Gm. | 0 3 Gm. | 0 25 Gm. |
| 10th | 0 3 Gm. | 0 25 Gm. | 0 3 Gm. | 0 25 Gm. |
| Total for Course | 2 45 Gm. | 1 95 Gm. | 2 65 Gm. | 2 05 Gm. |

For subsequent courses under either plan repeat the dosage of the first course

The Administration of Bismuth and Mercury Preparations Drugs and Dosage, Technic of Intramuscular Injection

Drugs and Dosage—In view of the many preparations of bismuth and mercury on the market, and of the high-pressure sales methods employed in their distribution, it is advisable for the general practitioner to confine his choice to the relatively few products which have already received a fair trial in the larger clinics, and to watch for reports appearing from time to time in the *J. A. M. A.* on the newer products. The use of products marketed by a few reliable drug manufacturers will reduce to a minimum the chances of administering preparations of uncertain toxicity and substandard therapeutic potency. If any lot or preparation gives trouble, samples from it should be sent to the manufacturers and to the Laboratory of the National Institute of Health in Washington for testing.

A Bismuth Preparations The efficacy of bismuth preparations appears to be proportional to the amount of elemental bismuth which they contain. For this reason it is best to use preparations containing not less than 50 mg of elemental bismuth in 1 cc. Two of the preparations which meet this and other requirements are

1 **Bismo-Cymol (NNR)** a basic bismuth salt of campho-carboxylic acid, in solution in olive oil. The salt contains between 37 and 40 per cent of elemental bismuth, and 1 cc of the oil solution contains 50 milligrams of bismuth.

2 **Sodium Potassium Bismuth Tartrate** A suspension in olive and almond oils with butyn, each cc containing 50 milligrams of elemental bismuth.

Either of the above preparations, given in initial doses of 1 cc, increased after a few injections to 2 cc, will give the patient a total of approximately 1,350 mg of elemental bismuth per course of 15 injections.

B Mercury Preparations The soluble mercurials act more promptly than the insoluble ones but are eliminated so rapidly that injections must be given daily or at most every other day, while with insoluble compounds suspended in oil, one or two injections a week will suffice. The preparations recommended here are

1 **Mercury Salicylate**, insoluble, containing about 55 per cent of mercury, suspended in a vegetable oil. The initial dose is $\frac{3}{4}$ grain, which comes prepared in a 1 cc ampule, this dose is increased to 1 grain and later to $1\frac{1}{2}$ grains (some patients will tolerate 2 grains). This gives the patient about 18 grains of the mercury salt per course of fifteen injections.

2 **Mercury Bichloride**, water soluble, containing about 73 per cent of mercury.

3 **Mercury Succinimide**, water soluble, containing about 50 per cent of mercury.

The dosage for either soluble preparation is $\frac{1}{8}$ grain increased to $\frac{1}{4}$ grain. At least five times as many injections of the soluble preparations would be required in order to provide the equivalent of a fifteen-injection course of the insoluble salicylate.

Mercury Rubs Mercury may be given byunction, in the form of blue ointment, put up in cascadelets, one cascadelet to be rubbed into one part of the body once a day after a hot bath. Rub for twenty to thirty minutes and change the site daily. Give in courses of thirty rubs.

Mercury by Mouth is less efficacious than by injection or unction but may be used in late forms of syphilis, especially for elderly persons, or for those temporarily out of reach of a physician. The following are recommended

- | | | |
|--------------------------|----|-----|
| (1) Hydrarg Chlor Corros | gr | iii |
| Potassium Iodide | ℥ | ss |
| Elix Lactopep q.s ad | ℥ | vi |
- (2) Pills each containing $\frac{1}{16}$ grain of mercury bichloride and 5 grains of potassium iodide

One teaspoonful t.i.d in glass of water fifteen to twenty minutes before meals
Sometimes better tolerated with pinch of sodium bicarbonate in each dose
One pill t.i.d preferably dissolved in a glass of water before meals

Mercury is not recommended for intravenous injection

Technic of Intramuscular Injection — Bismuth and mercury preparations are injected intramuscularly into the buttock, the preferred site being at or near the center of the upper inner quadrant

gage needle about $2\frac{1}{2}$ inches long. Holding the hub of the needle between the index finger and the thumb, with a quick wrist motion thrust the needle $1\frac{1}{2}$ to 2 inches into the gluteal muscle. The dose to be injected is then collected in the syringe, and, while the hub of the needle is held with the index finger and the thumb, the syringe is attached and the contents injected slowly.

Without removing the syringe, wet a cotton swab with alcohol and press it down firmly beside the puncture site, withdrawing the needle at the same time. Massage

Figure 3 Sites for intramuscular injection

Other sites which may be used are, in the order of preference (1) at or near the center of the lower inner quadrant (2) the upper outer portion of the upper outer quadrant.

With patient lying face downward on table, select the site of injection and clean the part with cotton saturated with 70 per cent alcohol. Use a 19 to 20-

Figure 4 Sites for intramuscular injection showing needle in place

vigorously and deeply without moving the fingers from the spot. Then using the outer part of the palm massage so as to move the entire buttock. Now put a small piece of cotton over the puncture wound and hold it firmly in place with a $\frac{1}{4}$ -inch strip of adhesive tape. Use alternate buttocks for subsequent injections.

WARNING! Before attaching the syringe, be sure to allow the needle to remain in place for 30 to 60 seconds, to determine whether or not the needle is in a blood vessel. If blood appears, withdraw the needle and puncture a short distance away. If an embolism occurs, the patient will cough and complain of pain, and chill and fever will follow. In severe cases an infarct will develop. If the infarct is large enough, a mild pneumonia will follow. Roentgen rays will usually confirm these findings.

Complications Due to Bismuth and Mercury Their Prevention and Treatment

A patient usually tolerates the heavy metals in proportion to the cleanliness of the mouth. We advocate having the teeth cleaned by a dentist and kept clean by brushing and the use of dental floss. It is also important to begin the course of injections with small doses and increase the dosage gradually. By this means much larger amounts can be given, whereas a high initial dosage is likely to be poorly tolerated. The bowels should be

kept open and fluids taken freely throughout the course.

If the gums show signs of irritation during the treatment, massage the gums several times a day, using table salt on the end of the finger. The appearance of a blue line during a bismuth course is not a contraindication to further treatment, but calls for more careful hygiene of the mouth and a reduction in the dose for the next few injections.

If a stomatitis appears, stop treatment immediately and irrigate the mouth with hot saline (several gallons a day), paint the gums daily with a 2 per cent solution of chromic acid, and as soon as tenderness has subsided sufficiently, massage the gums. Force fluids, keep the bowels open by means of daily saline laxative, and give sodium thiosulfate as for arsenic poisoning.

Kidney complications. Albumin and occasional casts, and (rarely) hematuria may occur under heavy metal therapy. In such cases it is best to discontinue all treatment for two or three weeks, and then change to the other heavy metal or to arsphenamine.

If the red blood count or hemoglobin becomes low under heavy metal therapy, it is better to change to arsphenamine, giving small doses not oftener than once a week, and increasing the dose gradually.

For complications due to faulty technic of injection, see "Technic of Intramuscular Injection."

Preventive Medicine

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M D , DR.P H , New York City

Editorial Note Under this title will appear short summaries of 'transition cases' from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies but will accentuate situations from the point of view of individual mental hygiene such as crop up in the everyday practice of medicine

The Deserter

Woman of thirty five with two children, nine and six.

Both her husband and her mother, who accompany her, praise her. She had been a good child, later a serious girl who worked as a bookkeeper before her marriage. She was active, efficient, and well liked by her employer. Six years ago, after the youngest child's birth, she "broke down" mentally, being depressed for about four weeks, but was "completely cured." The same thing happened two years ago for a few weeks.

Now, for the last half year, she is all changed. Her present condition began gradually and slowly became worse. She is restless and has lost interest in her family surroundings. From a lively, keen, nice mother and wife she has been transformed into a person who is neglectful about her dearest people and also about herself, her appearance and welfare. There are many moments when she fears "she is going to die" or "she is going insane." She feels "weak and weaker," physically and mentally. Her weight, while still within normal limits, has decreased. She left the children with her husband and his widowed and childless sister and is staying with her mother, a kind, serious, and reasonable-looking person.

"Yes, I love my children," patient says, "they are so wonderful, but I cannot say that I am anxious to see them. I hug them, but it is a strained feeling. When I look at them I say to myself, why don't I want to run to them? I

am unable to take care of them. I want to be happy, there are many good things happening in our family, one of my sisters is getting married, another is graduating from college and so on, but I am unhappy. No, I don't know of any reason why I became that way. It is true that our economic condition is bad, maybe that is the cause but I am not sure. My husband has always treated me well, but without love or warmth. We rarely quarrel and then it is because he belongs to several clubs and comes home late from meetings. Sometimes he leaves the house quietly when I am asleep, at about eleven. I am not jealous, he has no other women. I had nobody else before my marriage. No, I have no visions and hear no extraordinary sounds. I do have thoughts, but they're not thoughts, it's as if they're speaking." (A beginning of hallucination) "I try to do some work in my mother's house, but it is under strain and I must stop soon. My head is so dull. I keep thinking about myself only. From time to time I get an unexpected scare. Something looks like a coffin—and so on. I am hazy, in a daze, in a cloud or rather like in a net, outside the world, not part of it, not interested in it. I don't feel like doing anything. I like to see the day fly, but when I was well I liked to see the day linger. When people come to the house I don't care to see them. I don't enjoy any kind of company. The other day was my birthday and I was sure that it was my last one. I am fighting this idea, but it is there."

At a given moment she says "Don't I know that my fears are not real?"

No, she does not, not completely. Consciousness is side by side with unreality.

In some of the phases in this case, as in many others, mental depression and schizophrenia meet, and we must diagnose between both.

Save the spells of six and two years ago, the personal history of this patient is negative in regard to disease. The childbirths were normal. There is no one in the family suffering from any mind disturbance. Both parents are alive and active.

Patient speaks well, in a perfectly coherent and intelligent manner. Her memory and attention are good. She is a fine, cultured person. Officially she has finished high school, but is well read in addition to that. She is outwardly quiet both at home and in the examiner's presence, but cannot control her tears.

She does not remember her dreams very well. In one that she recently had she was at home and preparing cereal for her children. It is natural that that should be a wish. In another her husband was petting her and she "felt like nailed down through both ovaries"—an expression which is at variance with her usual way of talking.

Her menses are normal. Her blood pressure, heart function, and entire physical make-up show nothing abnormal. She is gynecologically normal. Does not complain about the sex relations, but says husband is cold. "I don't know why." She adds "I am faithful, have always been and have never gone out gallivanting." Yes, even when I was well and the few times I had a smile across my face, his contact was like embracing a lamp post. Of course, now I don't care. Everything seems slow motion and futile and irrelevant. I have quit the field *like a deserter*."

The management of this case demands, not only talks to the patient, but serious conversations to the family, whose behavior is the opposite of what it should

be. It must be explained that just now, until some improvement is seen, it is bad to force this patient with her tired mind to see people or to be socially active, that it is wrong to ask her to make an effort to act differently than she does and so to fatigue herself mentally even more, that it would never do to blame her for her condition or to tell her "it is nothing," etc. She needs kindness, understanding, hope for the future. Nobody around her should cry or show despondency. Nor should anyone be too boisterous or elated. One friend and frequent visitor wants patient to "crush her annoying thoughts." This is erroneous. All we can expect is that she pay no attention to them. They cannot disappear. They must be ignored if possible.

The husband must be told in which way he has erred and how he is to behave in the future.

The patient may be truthfully told that she is sure to get well, as the prognosis in these cases, for the near future at least, is favorable. But at the same time she should be watched, as an attempt at suicide or harmful action is not excluded.

She is at the brink of a psychosis, but she has not passed the threshold.

It has no sense to send her, as the family desired, to a lonely country place, which would do her harm. Her bowel movements must be under control. Some hydrotherapy, perhaps in the form of quiet, protracted lukewarm baths, is indicated. As long as she sleeps well and eats some food, there is no need of coaxing or forcing her or prescribing unnecessary medication.

The effect of her talks with her doctor was rapid and was evident from the first session, which, alas, does not happen often. The examiner felt it in the patient's hand—a response to his own clasp. He was pressing gentle friendship indirectly into her quivering and wounded mind.

Presidential Address

IS THE PRACTICE OF MEDICINE BECOMING TOO SCIENTIFIC?

WILLIAM A. GROAT, M.D., Syracuse

President Medical Society of the State of New York

SOME twenty years ago Southard, one of the first of the modern medical psychologists, chose for his topic for a speech of the day, "Is the Practice of Medicine Becoming More Scientific?" He talked with considerable insight and most interestingly, but in the end he was unable to answer the question, apparently because he found in some ways it had become more scientific and in other ways it had not. When he had added the plus and minus items he found no measurable gain to science. I am not merely paraphrasing his topic when I choose for mine, "Is the Practice of Medicine Becoming Too Scientific?" We might agree that the reframed question is the more suitable for today.

For many years medicine was comfortably divided into the science and the art. Clinical medicine as we now understand it was still another thing in the minds of many. We had professorships such as "Professor of the Science and Art of Medicine and Clinical Medicine." Was that title a declaration that the science of medicine and the art of medicine were separable and that there might be a third component, the application of these things clinically? If that were true could the clinical application of the science of medicine and the art of medicine be made separately, or must they be used together?

Gradually the idea developed that the science of medicine was a thing apart and the great progress in medicine must be along wholly so-called scientific lines. Scientific medicine was thought to be cold, dispassionate beyond, or above, this matter of human interest. The art of medicine was accepted as a necessary evil,

or as something for the relatively poorly trained or incompetent individuals to practice. It was a field which might be invaded with impunity by the quack, the poorly educated, the various cults, and other aberrant groups. It might even be mixed with religion. The science of medicine should not be linked with it!

George Sarton, in his essay on the *History of Civilization*, was quoted by Millikan before a recent forum on current problems, as saying "The main purpose of man is to create beauty, justice, truth." He recognized that "there have been in all times at least some men who were obsessed by the idea of creating beautiful things, which is art, of improving social conditions, which is philanthropy and righteousness, of discovering and disseminating truth, which is science." This is the summation of George Sarton's philosophy, and, as Millikan has said, "It is a philosophy with which most thoughtful men agree."

It is Sarton's idea of the "mission of mankind", and art, philanthropy, and science were thought to be independent of one another. Millikan was willing to agree that so far as the first of them, art, is concerned it may still be regarded as independent, as something probably separate and distinct. He doesn't agree, however, that justice and truth can be separated. Science is truth, and "without truth social justice is meaningless." Without the scientific background of truth, devotees "with what they would call ideas for 'social justice' are "just as likely to exert a socially pernicious influence as a whole some one." Millikan directs attention to the fact that even "with the best of in

*Delivered at the 18th Annual Meeting of the Medical Society of the County of Monroe
December 20 1933*

tentions they have done so repeatedly" all through history and that "they are doing so today because they do not know enough of the truth, the basis for all straight thinking, to bend their efforts to what is actually in the interest of social well-being"

I think that we as physicians may well consider that, for I think we will agree that science and the seeking after truth cannot be divorced from those things which are philanthropic, charitable, and righteous

Indeed, "both good will and knowledge are vital to human progress" Is it not true, much as Millikan has said, that knowledge is the more important, "for do not most people mean well, few are sufficiently well informed to do well?" Progress depends upon the spread of knowledge and that knowledge must be a broad base under all that we call philanthropy and all that we call righteousness, and from these there must be an equal return to science It seems clear, too, that the increase of knowledge just as it increases the extent of the universe increases the beauty, the scope, the progress, the betterments, the artistic attainments and strengthens the social fabric

But what about art? Is art really independent? As the art of medicine, can it possibly be divorced from righteousness and philanthropy or from science?

In thinking of medicine and medical progresses based upon its science and in neglecting to think of the progress of medicine as also based upon its art, we may have overlooked the fact that what we call the art of medicine is the backbone of the theory that doctors should be interested in all the humanities of medicine

We may have failed to realize that the serving of human needs through any medically connected agency should be under the direction and control of those who have knowledge, those who know what they are doing The humanities of medicine, if for no other reason, cannot be left to those who lack scientific knowledge and scientific training It is possible that those things which we call social benefits and our community obligations

offer the greatest field for scientific progress in medicine

We may divide medicine into its parts We have what we call the pure science part, so closely allied to the basic sciences, and we have the science laboratory researcher who never sees a whole human being, merely a piece or a slice of him, and may not even be a doctor Many extremely valuable contributions have been made by this group Their work sounds like strictly systematic science but human interest is involved in it otherwise it would not be medicine Remote as it may seem to the capable workers in this narrowed field, the human contacts are there

We have another important group, the experimental medical group These men are wholly detached from the medical care or treatment of human beings They are the ones who carefully try out theories, evaluate new methods, discover new hormones, explain the hitherto unknown in the functions of the human body, but they do not treat Their observations on the living are on the experimental animals These groups too have thought that they are wholly detached from medical practice, but so many are connected with hospitals and with schools where practitioners are taught, so many of them although they may never have practiced medicine have worked out such marvelous medical things for humanity, that much as they may shake their heads, the human interest obviously is there They have been attached to the art of medical practice for they see in their minds the clinical picture

There is still another scientific group which has greatly aided in the discovery of new facts and has been a valuable connecting link between the fundamental medical sciences, experimental medicine, and the practice of medicine These are clinical investigators

A clinical investigator customarily works in hospital wards and laboratories He sees sick people, he welcomes them, talks with them, treats them as patients and all the time with advantage to them, keeps fine clinical records which he studies

carefully He watches the clinical indices of disease under controlled conditions, he weighs the food, he examines the fluids and the outputs, he analyzes the gases, but he is nware of human relations. He must practice the art of medicine not only in order to get the co-operation of his patient but in order to have knowledge of what may be going on in the mind of that patient and what psychologic disturbances are to be pictured therein

In clinical investigation unless the experiment is well conceived, unless the conditions of the experiment are maintained, unless the observations are carefully recorded, there can be no final considerations, deductions or conclusions acceptable in form as something to be added to the total of medical knowledge. There are plenty of men interested in medicine in one way or another along these scientific lines, who may be devoting their entire lives to it. Medicine as a pure science, as an experimental science, and as a clinically investigative science indubitably has become more scientific. It cannot be in these relations too scientific, too careful, too painstaking. Medicine must not make rash experiments, rush to ill-conceived conclusions, or yield to lay impatience, for the welfare of masses of human beings is at stake.

There are those that would have the government take over the financial control of medical research and medical teaching. Were such a thing to happen in its entirety the loss to education would be serious. Lay control can be most helpful, such associations most stimulating. There are lay persons and groups taking interest in medical science and teaching, who have the wisdom to devise large sums of money under private control in such a way that scientific thought is stimulated and work may be performed in comfort, unhurried, free from investigating commissions and bureaucratic hushbodies. Governmental control with its political preferments can and has produced that type of scientists who conched in marble halls become, as Hans Zinsser has said, "As unproductive as a hen sitting on a china egg."

We have in the practice of medicine the large group to which you and I belong, and it includes those who appreciate as far as they are scientifically able the work of the investigator and the researcher. We try to evaluate things after the clinical investigator has gotten through with them and make use of them for our patients. We give the clinical trial. The art of medicine is the making of that which is necessary for the patient to have, do, or have done for him as agreeable to him as possible. Until we carefully grade our work, until we are wholly resistant to the detail men, until we have been entirely purged of the desire to buy some new, shiny device which either whirs or spins, in order to impress our patients, we have not become too scientific.

Should every doctor be a researcher? Must every patient be treated as a subject for clinical investigation of research type? Must an elaborate control be attempted, elaborate equipment supplied, repetition after repetition made of what should otherwise have been a once or twice rechecked simple procedure? If so, it would be unscientific. The saying is that everything in this life worth while is either wrong, expensive, or injurious. The quasi scientific mode of procedure is wrong, expensive, and injurious. It is all of these to both patient and physician. Too much of the cost of medical care is of the unnecessary type and the whole science and art of medicine suffers because of it. No need to apologize for or qualify this statement. You know what I refer to and that no slighting of the interests of the patient is to be countenanced.

This overgrowth and emphasis leans toward disparagement of the honest efforts of well informed men to care for patients as simply, as efficiently, and as carefully as can be, and, we may add, as cheaply as possible for the good services to be rendered. What is more, much of the criticism of medicine today both true and false has come to it through the unnecessary costs, the unnecessary procedures, and the thoughtlessness which has entered into a noble profession.

Those who talk of full governmental control desire to make the practice of medicine seem as complicated and costly as possible, then to turn about and offer bureaucratic control as the only recourse.

The transition which has come and the degradation of those almost holy things in the practice of medicine in its purity and simplicity are what brings the scientific average down. There is lacking that union of the creation of beauty, justice, and truth which is the destiny of man. There is distinct scientific loss here. This defect is being recognized by medical schools and remedied. Not only must the student of today go to the laboratories and the basic sciences, he must also make contacts with patients in the wards as clinical clerks or whatever they may be called, and as seniors they follow the patient into the home, they study his family, his surroundings, his job. They try to know these things about him as a whole and to determine the clinical status of the patient by such an evaluation of him and his environments. Like the family physician of old he becomes an adviser, a counselor, and an altogether friendly influence. When he studies medical psychology, public relations, and the obligations of the physician as a citizen, he finds that these too are interwoven into the fabric of medicine. He may now practice with the erudition of today and the tenets of the Greeks, the tenets of his father and of his grandfather who preceded him in practice, and be truly scientific.

Medicine has been unscientific as we

have thrown away so much of the human relation stuff, just as we threw away the vitamins in what was thought to be the useless husk, the essential minerals which were in the pot liquor. Major effects are frequently produced by the smallest ingredient.

It is those seemingly small but very precious things which we have turned over to the inexperienced intern, the nurse, the social worker, the record keeper, the switchboard operator, the pharmaceutical houses, the prepared food merchandisers, the medical machinery manufacturer, the dietitian, the laboratory technician, the x-ray technician, the physiotherapist, the masseur, that has left the ordinary practice of medicine so unscientific and so tasteless. We have put the things which should have been treated with great scientific care into the hands of the less expert, even of the inexperienced, the ignorant, the willfully exploiting. They increase the costs and they help us to make tons and tons of our records just so much wastepaper.

The destiny of medicine is to march with the advance of civilization and is one of the strongest forces in it. Therefore its main purpose is to create beauty, justice, truth. There must be at all times in the practice of medicine at least some men who are obsessed by the idea of creating beautiful things, which is its art, of improving social conditions, which is its philanthropy and righteousness, and of discovering and disseminating truth, which is its science, and the three are one.

1939 ANNUAL MEETING, ANNOUNCEMENT OF AN INNOVATION

At the forthcoming Annual Meeting of the Medical Society of the State of New York, the newly formed Section on Gastroenterology and Proctology will hold its first session and for its first day has decided to conduct a type of meeting new to our Society, but which has proved of interest in other similar organizations in the past few years.

The morning will be devoted to a Round Table discussion of subjects to be submitted in advance by any members of the State Society who expect to attend the meeting. A

round table group of speakers, consisting of two gastroenterologists, an internist, a surgeon, and a roentgenologist will discuss the previously submitted subjects in turn, supplemented by brief discussions from the floor. This type of meeting should provide an interesting innovation.

It will be much appreciated by the officers if members of the Society will send in questions for discussion either to the Chairman, Dr. A. F. R. Andreson, 88 Sixth Avenue, Brooklyn, or to the Secretary, Dr. John L. Kantor, 145 West 86th Street, New York City.

Public Health News

J ROSSLYN EARP, L R C P, Dr P H
New York State Department of Health

Our Part in the Control of Cancer

ON Nov 28 and 29, the district health officers and the directors of the several divisions in the central office met in conference at the State Institute for the Study of Malignant Diseases at Buffalo.

Doctor Godfrey gave two reasons for calling this meeting. He told the health officers that he did not want them to forget that they are doctors. He does not expect public health administrators to be at the same time specialists in orthopedics, in cancer, in syphilis, and in tuberculosis, but they must know what is going on in these fields. There are public health problems which lie outside the realm of vital statistics. Our job is to reduce morbidity and to postpone death.

In the second place, Doctor Godfrey said, he wanted the officers of the Institute to know that the Department has an organization in the field which may be of service to them. Education of the public in cancer is just one thing. Another is help that may be afforded in the follow up of cases that have been under treatment. He foresaw the eventual establishment in each district of a register of cancer cases, just as at present there are registers of the cases of syphilis and of tuberculosis.

The policy of the Institute is to concentrate on the treatment of primary cancer, to eliminate all hopeless cases post operative cases with no recurrence, and benign cases where feasible. Treatment is free to residents of New York State. Residents of other states are not accepted for treatment or examination. Each patient must be referred by a physician who is requested to make application for admission giving the following information:

- 1 Name, address, age of patient
- 2 Location of lesion and extent of disease
- 3 Physical condition of patient (state whether or not patient is ambulatory)
- 4 Factors and dates of treatment, if irradiation has been given
- 5 Operative findings and slide, if operation has been done (state extent of recurrence)
- 6 Biopsy report and slide, if biopsy has been done and tissue has not been sent to our laboratory

Although too many cases still arrive at the doors of the Institute in a late, incurable stage, Doctor B T Simpson told us that there is encouraging evidence that family physicians do make early diagnoses when they are given the chance. Three cases of cancer of the cervix have recently been referred in a stage so early that the Institute's experts could not make a clinical diagnosis, but in each case biopsy proved the presence of malignant growth. There was some discussion in the conference on possible danger of spreading cancer cells by performing biopsies, a danger which had been impressed on several of us in our surgical adolescence. Dr Simpson stated categorically that at the Institute they have never observed any detrimental effect from biopsies. The use of Lugol's solution on the cervix was recommended as a screen process though it was pointed out that any morbid condition that will remove glycogen from the epithelial cells will show an area that fails to take the iodine stain. In making biopsy sections we were advised to select tissue from the edge of the suspected area so as to in

clude some normal tissue in the stage of invasion

The question of preoperative radiation was brought up by Doctor Godfrey. Doctor Simpson pointed out that some of the surgical difficulties, especially in skin suture, caused by preoperative radiation are due to faulty technic. The Institute favors preoperative radiation but recommends that subsequent surgery should not be delayed.

We were privileged to make a tour of the Institute and to view its facilities. One could not help being impressed with the thorough organization as a result of which radium and x-ray plants are kept in almost perpetual therapeutic use. The essential place taken by the resident physicist in controlling by constant checking of apparatus the exact dosage of radiation administered was also impressive. Finally one could not help wishing that where public money is being so efficiently spent there might be no stringency due to lack of capital outlay. Of the three high-power x-ray machines one is seventeen years old, another eighteen years old. The Institute needs two new machines of 200,000 volts each, two of 550,000 volts, and one of 1,000,000 volts. An important research problem is the determination of biologic advantages of the new one-million-volt plants which have now become available at a price within the purchasing power of a state.

Of What Kind Should State Medicine Be?

"Medical care for persons on relief has frequently been largely emergency treatment for acute illness and has all too often been predominantly palliative." This complaint was registered by Dr. Ernest L. Stebbins, Assistant Commissioner for Preventable Diseases, New York State Department of Health, at a public dinner meeting held in the Onondaga Hotel at Syracuse on December 14. By considering the number of persons gainfully employed in this State who are not required to file income tax reports because of in-

sufficient income and from the records of T E R A, Dr. Stebbins made a rough estimate that there are some two million people in the State of New York who have insufficient income to make their own provision for medical care. The amount of disabling illness may be reduced by preventive measures: immunizations, industrial and environmental hygiene. The need for long continued palliative treatment may sometimes be avoided if facilities for adequate therapy are promptly available. For public medical service whether preventive or curative, the family should be considered as a unit. Health supervision must be maintained at all ages and for both sexes. In the provision of diagnostic facilities and for hospital care existing centers should be used to the fullest possible extent. Similar centers should be developed in rural areas not now supplied. The centers could be used for general health supervision, operated by the local medical profession with provision for reasonable compensation. In answer to a question the speaker made it clear that he favored routine medical examinations. There should be a system of "screening" to prevent overcrowding of the diagnostic centers where detailed case study would be undertaken. Government subsidy will be needed if free hospital beds are to be available in all areas. Special hospitals and treatment centers are needed if the control of cancer is to progress. Hospitals, treatment, and training facilities are needed for care of physically handicapped children, especially those in need of orthopedic care or suffering from heart disease. Dr. Stebbins concluded with the following caution:

"The development of a program of medical care for the medically indigent is an undertaking of such magnitude, and experience in this field is so limited and the disastrous effect of failure due to inadequate planning is so obvious that it seems definitely desirable that any plan for the development of a system of medical care for the medically indigent be started on a small scale or in a limited area and that it be expanded gradually as experience

and knowledge of administration is gained through actual practice"

The dinner was sponsored by the Health Division, Syracuse Council of Social Agencies and was addressed first by Dr Peter Irving and then by Dr Stebbins. A short discussion followed.

Operative Obstetrics and Stillbirths

Seven years ago J V de Porte¹ observed that babies in upstate New York are subject to a greater risk of being still born if they arrive between 3 P M and 6 P M than if they are born at any other hour of the day or night. His study was made on statistics recorded during the year 1929. J Yerushalmy who has recently left our department to work for the U S Public Health Service confirmed Dr de Porte's earlier observations working with statistics for 1936.² He found that both neonatal deaths and

stillbirths struck with greatest force the infants born between 3 P M and 5 P M. Since in the meanwhile various obstetricians had suggested that the afternoon hours might be loaded with an extra number of operative deliveries, Dr Yerushalmy also investigated this point. Through the co-operation of Dr Archibald Dean, District Health Director for western New York and Dr Thomas J Duffield, Registrar of Records for the New York City Department of Health, he was able to draw up tables showing the frequency of operative procedure by hour of birth. Operative obstetrics it seems are most frequent at two different periods in the day—one around eleven in the morning and the other between 3 P M and 5 P M. Dr Yerushalmy is careful to say that a correlation does not prove cause and effect. The statistics do, however accord with certain preconceptions which some obstetricians have advanced.

¹ de Porte, J V. *Am. J. Obst. and Gynec.* 23:31 (January, 1932).

TYPHOID MARY DIES

The death on November 11 of Mary Mallon aged seventy who achieved notoriety as the first typhoid carrier recognized in the United States brings to a close a strange history. observes the *J.A.M.A.* "Typhoid Mary" was a cook whose employment was almost invariably accompanied by an outbreak of typhoid. Her rôle in the spread of this disease was finally recognized in 1907 and she was forcibly kept out of circulation at the Detention Hospital of the Health Department for three years. Following her voluntary release in 1910 she disappeared for five more years and although her history neither before her first detention nor after her disappearance could be learned completely she was known to have caused at least ten outbreaks of typhoid with fifty-one cases. From 1916 until her recent demise she was held by the New York City Department of Health in the Riverside Hospital on North Brother Island. She became reasonably adapted to her changed status, and her stools were constantly used by the health department as a control for mediums used in the culture of typhoid bacilli. Typhoid Mary will be known forever in association with the typhoid carrier problem.

BLOOD BANKS ARE SAVINGS BANKS TOO

Blood banks in New York City hospitals have developed into one of the least expensive of life-saving measures representing savings of more than \$200,000 a year for the taxpayers.

Storage of different types of blood by means of a harmless chemical and refrigeration make possible the development of the so-called blood banks.

Friends and relatives of patients needing transfusions volunteer the blood.

So excellent has been the response that the estimated cost of blood transfusions for a year will be reduced from \$225,000 to \$20,000 a year or less. Instead of giving money for taxes to support the cost of blood transfusions, the taxpayer may now give of himself.

With the cost of transfusion becoming a negligible item, its therapeutic use has widely expanded. Instead of being a measure used in the last extremity blood transfusions are used to hurry convalescence thus making further savings in decreased hospitalization days.

This has already been indicated by the number of transfusions in 1938, which totaled 10,465 for the first eleven months compared to 8,943 for all of 1937.

The Woman's Auxiliary

To the Medical Society of the State of New York

County News

Kings

Mrs Milton Bergmann was elected president of the Woman's Auxiliary to the Medical Society of the County of Kings, at the meeting held in the Medical Society Building on December 13, 1938. Mrs George Clark former president of the Woman's Auxiliary to the Medical Society of the State of Indiana was an honored guest. Mrs Bergmann, the new president, spoke on the meaning of the caduceus. Another interesting feature of the afternoon program was the showing of baby pictures of the members of the auxiliary and an exhibit of their needlework and hobbies. A social hour followed the executive session and program.

Rensselaer

Mrs James Donnelly, president of the Woman's Auxiliary to the Medical Society of the County of Rensselaer, was elected for a second term at the annual meeting, held in the Samaritan Hospital on Dec 13, 1938. Miss Grace E Allison, Superintendent of the Hospital, spoke on "Ideal Hospitals and Social Welfare."

Queens

The installation of the officers of the Woman's Auxiliary to the Medical Society of the County of Queens took place on Wednesday Evening, December 28, in the Medical Society Building, Forest Hills. Dr Henry Eichacher, retiring

president of the Medical Society greeted the guests and presented Mrs Elmer Kleefield retiring president of the auxiliary with her pin. Dr Joseph Wrana, newly elected president of the Medical Society welcomed Mrs William Lavelle and her new board. Dr Wrana spoke of the work the auxiliary had done and of the value of an auxiliary to its Medical Society and to the Medical Profession.

Mrs John Mahoney was in charge of arrangements.

Saratoga

Mrs Mark Nettles was elected president of the Woman's Auxiliary to the Medical Society of the County of Saratoga at the annual meeting held on December 5. She succeeds Mrs G Scott Towne first County Auxiliary president who is now president-elect of the State Auxiliary and who takes office as president at the Annual Convention of the State Auxiliary to be held in April, 1939, in Syracuse.

Mrs Leslie Sullivan, president of the Woman's Auxiliary to the Medical Society of the County of Schenectady was the guest speaker. She gave an interesting account of the activities of her own auxiliary.

The article which appeared in the January 1 issue was written by Mrs Luther Rice, Organization Chairman of the State Auxiliary

"CHEAPER" IS RIGHT

The headline, "Eight States Get Cheaper Medical Care," which one Ohio daily used on an article regarding various medical service plans, seems to summarize just what is likely to happen—cheaper medical care—if the crack-pot schemes which are being suggested by some reformers ever take root.—*Ohio State M J*

NO "DOCTOR IN THE HOUSE"

The cry "Is there a doctor in the house?" will not get a ripple in either branch of the 1939 Legislature. Not a physician is seated in either chamber, says an Albany dispatch. If any physicians ran for the legislature, the voters paid them the delicate compliment of deciding they could not be spared from the home town.

Medical News

Allegany County

The new officers of the Allegany County Medical Society for 1939 are as follows: president, Phillips I. Morrison, Bolivar; vice-president, J. Paul Reims, Belmont; secretary, Edwin F. Comstock, Wellsville; treasurer, Roger W. Blaisdell, Wellsville.

The following were re-elected to the Board of Censors: George W. Batt, Hanford; K. Hardy, William F. Reedy, Sam B. Scott, and Elmer S. Webster.

Delegate to the State Society: Lyman C. Lewis, Belmont; alternate to the State Society: N. H. Fuller, Friendship.

Bronx County

The scientific program of the Bronx County Medical Society on December 21 was as follows:

Symposium on Voluntary Health Insurance: (A) Cooperative Health Associations, Dr. Kingsley Roberts; (B) The Next Step, Dr. Chas. Gordon Heyd; (C) Discussion, Dr. M. J. Goodfriend, Dr. Solomon Kreil, and Mr. James R. Garrett.

The North Bronx Medical Society on January 5 listened to addresses on 'Anxiety Hysteria,' by Dr. Jacob H. Friedman; 'Coronary Thrombosis,' by Dr. Herman L. Frosch; 'Beta Hemolytic Streptococcal Meningitis and Septicemia of Otic Origin Treated by Sulfanilamide,' by Dr. David L. Frey, and 'Impotence and Sterility in the Male,' by Dr. Max Huhner.

Broome County

These officers, chairmen of committees, censors, delegates and compensation board were elected at the Annual Meeting of the Broome County Medical Society, on December 13: president, Charles L. Pope, Binghamton; vice-president, Charles M. Allaben, Binghamton; secretary, Rolland C. Bates, Binghamton; asst. secretary, Mark H. Williams, Binghamton; treasurer, Elton R. Dickson,

Binghamton; asst. treasurer, Edward M. Jones, Endicott.

Chairmen of Committees: Economics, Harry I. Johnston, Binghamton; Legislation, Chalmer J. Longstreet, Binghamton; Library and History, Stuart B. Blakely, Binghamton; Membership, Clifton H. Berlinghof, Binghamton; Milk Committee, Perry H. Shaw, Binghamton; Public Relations, Blinn A. Buell, Binghamton; Public Health, George S. Lape, Binghamton.

Censors: Stuart B. Blakely, Binghamton; John J. Cunningham, Binghamton; Frank M. Dyer, Binghamton; Silas D. Molyneux, Binghamton; Charles D. Squires, Binghamton.

Delegates: Samuel M. Allerton, Binghamton; George C. Vogt, Binghamton.

Alternates: Clifton H. Berlinghof, Binghamton; Charles M. Allaben, Binghamton.

Compensation Board: Harry I. Johnston, Binghamton; Frank M. Dyer, Binghamton; Lionel O. Smith, Johnson City; Howard P. Griffin (one year) to replace Frederick M. Miller, resigned.

Chautauque County

Dr. Howard L. Prince, chief of staff, Rochester General Hospital, spoke on 'The Diagnosis and Treatment of Intestinal Obstruction' at the December dinner meeting of the Jamestown Medical Society at Hotel Jamestown. Dr. Homer M. Wellman presided and introduced the speaker. Dr. George W. Cottis opened the discussion period.

Chemung County

The Chemung County Medical Society elected officers and voted a constitutional change lightening the restriction on membership of foreign born physicians at its annual meeting on December 7 at the Arnot Ogden Memorial Hospital.

The constitutional change was made because of the persecution in other countries of physicians who may wish to become U. S. citizens. In the past, it has

been necessary for a physician to have his final citizenship papers, involving residence of at least five years, before becoming eligible for membership in the county society

In the future he will be eligible for membership if he has taken out his first citizenship papers

The following officers were elected, all of Elmira: president, Rene Breguet, vice-president, George R. Murphy, secretary, Robert J. Lawler, treasurer, Sven L. Larson, delegate to state society, Elliot T. Bush, alternate, John F. Lynch, delegate to 6th district, Donald J. Tillou, alternate, Floyd E. Woodhouse, member board of censors, Alfred J. Westlake, member board of trustees, Charles F. Abbott.—*Reported by Robert J. Lawler, M D, Secretary*

Erie County

Dr. Howard B. Sprague, of Boston, addressed the Buffalo Academy of Medicine on December 14 on "What Price Coronary Thrombosis?"

Franklin County

Dr. Edward R. Baldwin, dean of the Saranac Lake medical profession, has announced his retirement as director of the Trudeau foundation and Trudeau school after 22 years of service.

Although head of the foundation since its beginning in 1916, Dr. Baldwin has been identified with Trudeau sanatorium since 1893 when he came to Saranac Lake and has played the major rôle in the history and development of the institution, as a colleague of the late Dr. Edward Livingston Trudeau.

At the same time, Dr. Baldwin announced that Dr. LeRoy U. Gardner, director of the Saranac Laboratory, will succeed him as director of the foundation and the school.

It was also announced that Dr. Francis B. Trudeau, vice-president of the sanatorium, will serve as chairman of the medical board and Dr. F. H. C. Heise will continue in office as medical director.

Genesee County

The Annual Meeting of the Genesee County Medical Society was held December 8. There were twenty-five physicians present.

The paper was given by Dr. R. Plato Schwartz of Rochester, on "Backache and Sacroiliac Lesions."

The following officers were elected for 1939: president, G. Henry Knoll, LeRoy, vice-president, Eugene G. Ribby, Byron, secy-treasurer, Peter J. Di Natale, Batavia, delegate, Peter J. Di Natale, Batavia, elected last year for two years.

Steps are going ahead for survey of medical needs.—*Reported by Peter J. Di Natale, M D, Secretary*

Jefferson County

At a meeting of the Jefferson County Medical Society on Nov. 10, the following officers were elected: president, James E. McAskill, Watertown, vice-president, Harold L. Gokey, Alexandria Bay, secretary, Charles A. Prudhon, Watertown, treasurer, Walter F. Smith, Watertown.

Board of Censors: Harlow E. Ralph (Belleville), Carl B. Alden (Adams), Jesse R. Pawling (Watertown), David G. Gregor (Watertown), and Murray M. Gardner (Watertown).

Delegate to the State Society: C. A. Prudhon, Watertown, alternate to the State Society: Norman L. Hawkins, Watertown.

Delegate to the Fifth District Branch: Howard N. Cooper, Watertown, alternate to the Fifth District Branch: S. E. Douglas, Adams.

Members of the Medical Society of Jefferson County gave five-minute résumés of "What's New in 1938" in various fields of medical science at the regular monthly meeting of the society on December 8 at the Black River Valley club. Discussion and questions followed presentation of each report.

Those reporting on the year's scientific gains and their topics were as follows: "Surgery," Dr. H. N. Cooper, "Obstetrics and Gynecology," Dr. W. D. George, "Internal Medicine," Dr. W. W. Hall, "Pediatrics," Dr. Norman L. Hawkins,

"Ophthalmology," Dr L E Henderson, "Roentgenology," Dr T N Sickels, "Otolaryngology," Dr C. A Prudhon, "Tuberculosis," Dr S E Sumpson, "Urology," Dr W W Young, Social Diseases," Dr L R Smith

The meeting was preceded by dinner at 6 30 P M.

Kings County

Twelve Brooklyn physicians, members of the Red Hook-Gowanus Health Center Advisory Board of the Board of Health, have resigned in a body from that board as the result of differences with Health Commissioner John L. Rice. Dr Pasquale J Imperato, member of the board, in an address at the twelfth annual meeting of the South Brooklyn Medical Society said the resignations were presented to protest "incompetent treatment" of syphilis patients at the center, which has a capacity of 1,000 patients and treats 4,500. He said Dr Rice had rejected a suggestion that volunteer private physicians be called in to treat the cases at \$1 each to relieve the center's staff

Fifty years of medical practice by Dr J Richard Kevin of Brooklyn were celebrated by his friends at a dinner at the Hotel St. George on December 10

Dr Laura M. Riegelman, of Brooklyn, who is retiring from the Department of Health after thirty-one years of service, was honored at a dinner on December 7, attended by more than two hundred medical inspectors health officers, and friends

The Richmond Hill High School is giving a semi professional course to train doctor's office assistants

Monroe County

Three days, January 11, 12, and 13, were devoted to dedication ceremonies, open house, and special meetings in connection with the opening of the new home and auditorium of the Rochester Academy of Medicine at 1441 East Avenue.

New York County

"Vitamins, with Special Reference to Therapy" will be the topic at the meeting of the New York Academy of Medicine on February 2. The speakers will be Drs. Arthur M. Yudkin, Norman Jolliffe, and Gilbert Dalldorf. Discussion by Arthur J. Pntek, Jr., Soma Weiss, and Philip Finkle

Topics and speakers at the Friday afternoon lectures at 4 30 at the New York Academy of Medicine will be January 20, "Breast Cancer," Dr Frank E. Adair, January 27, "Toxemias of Pregnancy," Dr Arthur M. Fishberg, February 3, "Laboratory Aids," Dr William S. Tillet.

On December 20, 1938, the Council of the City of New York adopted the following

RESOLUTION OF RECOGNITION OF THE PART PLAYED BY THE SEVEN THOUSAND PHYSICIANS OF THE CITY OF NEW YORK FOR PROTECTION OF THE PUBLIC HEALTH

which was presented by Messrs Sharkey and Cashmore—

WHEREAS In the City of New York there are 7 000 physicians working day and night to keep people well and

WHEREAS, They have no cornerstone to lay nor a public official to praise with florid speeches their deeds. These are limited to praise of municipal health agencies, and

WHEREAS, Emphasis is laid on the City work in reducing mortality and sickness through units sponsored by the City with a woeful disregard of the part played by the private practitioner and

WHEREAS, It is considered unethical for individual medical men to publicize themselves nor have they inclination or opportunity to sing their own praises now therefore be it

Resolved That we members of the City Council do hereby take official cognizance of the great part played by the forgotten 7 000 private practitioners in this city in the reduction of sickness disease, and the death rate and deplore any attempts which may be made to minimize their great contributions and be it further

Resolved That a copy of this resolution be sent to the official medical society in each County of the City of New York.

Referred to Committee on Rules,

Dr Maurice J Sittenfield, of New York City, who died on December 1, was one of the first to introduce x-ray therapy into this country and one of the first to use x-ray and radium in the treatment of cancer

Dr William Miller Ford, surgeon, former president of the St. Vincent's Hospital medical board, and director of the gynecology and obstetrics departments at St Vincent's since 1927, died of a heart ailment at his home, 55 E 86th St, in November, aged sixty

Dr Ford, a native of Brooklyn, was consulting gynecologist for the New York Hospital for the Ruptured and Crippled for seventeen years, and was chief surgeon and director of the Manhattan Maternity Hospital when it was merged with the New York Hospital group. He was also consulting gynecologist for St Clare's Hospital, and a former professor of obstetrics at New York University

Niagara County

The Niagara County Medical Society has approved in principle the medical indemnity insurance plan

Oneida County

A series of six lectures on heart disease, under the auspices of the Medical Society of the County of Oneida, have been given by authoritative speakers from New York City at the Utica State Hospital from November 30 to January 4

Five district meetings have been held in various parts of Oneida County, in co-operation with the County Medical Society, in an educational campaign against pneumonia

Ontario County

Advances in treatment of cancer were listed and described on November 17 by Dr George T Pack, of New York City, speaking before the 16th annual dinner meeting of the Geneva Academy of Medicine at the Hotel Seneca

Dr E C Merrill was host to the Canandaigua Medical Society on November 17, in the Canandaigua Hotel. Dr

Adrian S Taylor of Clifton Springs read a paper on "Empyema"

Otsego County

The Otsego County Medical Society has endorsed the movement for seven more public-health nurses in the county, in addition to the two now on duty

Putnam County

Dr John E Heslin, Professor of Urology at Albany Medical College, addressed the Putnam County Medical Society upon "Urological Problems in General Practice," at the monthly meeting on December 7 at Carmel Country Club—*Reported by John T Jenkin, M D, Secretary*

Queens County

Queens physicians gave a testimonial dinner at the Pomonock Country Club in Flushing on December 14 to celebrate the fifty-two years of medical service of Dr George K Meynen, of Jamaica

These officers were elected at the annual meeting of the Medical Society of the County of Queens on November 29: president-elect, William T Berry, Long Island City, secretary, Frank R Mazzola, Jamaica, asst secretary, Chester L Davidson, Jamaica, treasurer, Daniel J Swan, Flushing, asst. treasurer, Bernard Davidoff, Long Island City, historian, Carl Boettiger, Flushing, directing librarian, Carl Boettiger, Flushing, asst., William Benenson, Flushing, censors, Edward C Veprovsky (3rd district), Leo G Goldberg (4th district), Samuel Dillon (5th district), Jacob Werne (at large), trustees, James M Dobbins, William J Lavelle, James R Reuling, Jr, delegates, W Guernsey Frey, Jr, H P Mencken, alternates, Elmer A Kleefield, William Benenson, John J Sheehy

The following will remain in office: delegates, James M Dobbins, Frank R Mazzola, James R Reuling, Jr, Joseph Wrana, alternates, Walter L Lynn, Charles S Miller, Daniel J Swan, trustees, Thomas M d'Angelo, Henry C

Courten, Herbert L. Langer, Francis G. Riley, Albert L. Voltz, censors, Raymond L. H. Murphy (2nd district), Edward C. Steiner (1st district), John F. Wolfram (6th district), Robert R. Yanover (nt large)—*Reported by Frank R. Mazzola, M.D., Secretary*

The Medical Society of the County of Queens is giving a free course in medical Italian at the Society's building at Forest Hills.

Richmond County

The Annual Meeting of the Richmond County Medical Society was held on December 14, at the Richmond County Health Center, and the following officers were elected: president, Frederick M. Schwerd, M.D., vice president, Herbert A. Cochrane, M.D., secretary, John K. Lucey, M.D., treasurer, Curtis J. Becker, M.D., censors, Charles E. Pearson, M.D., Andrew J. McGowan, M.D., Nathanael Fedde, M.D., delegates to state society, Arthur S. Driscoll, M.D., Stanley C. Pettit, M.D., alternates, Erna S. Enderle, M.D., Else T. Marcus, M.D., Christopher J. DiCrocco, M.D., delegates to 1st district branch, Robert M. Shields, M.D., Florence T. Donovan, M.D., alternate, Christopher J. DiCrocco, M.D.

The presidential address given by Dr. Schwerd was on medical economics, and Dr. Becker submitted his treasurer's report from December 3, 1937, to December 1, 1938, showing total receipts of \$2,622.09 and disbursements of \$2,644.57.

The New York City Department of Health has given the Society the use of the auditorium in the Richmond County Health Center for meetings, and has also provided the Society with an office for its own use in the building.

Rockland County

These officers were elected at the annual meeting of the Medical Society of the County of Rockland on Dec. 6: president, Julius Pomerantz, Spring Valley, vice president, Russell E. Blaisdell, Orangeburg, treasurer, Dean Miltimore Nynck,

secretary, William J. Ryan, Pomona. Chairmen of committees: membership, John W. Sansom, Sparkill, legislative, John C. Dingman, Spring Valley, public health and public relations, George M. Richards, Stony Point, scientific work, E. Hall Kline Nynck, medical economics, Harold S. Heller, Spring Valley.

The following were elected at the annual meeting on December 1, 1937, Spring Valley, N. Y., for two years: board of censors, 1938 and 1939, chairman, Alexander N. Selman, Spring Valley, vice-chairman, George W. Unsworth, Suffern, Russell E. Blaisdell, Orangeburg (Dr. Blaisdell replaced by Matthew J. Sullivan of Haverstraw 12/6/38), Royal F. Sengstacken, Suffern, Orville N. Lewis, Haverstraw, Delegate to State Society, Stephen R. Monteith, Nyack, 1938 and 1939, alternate delegate, William J. Ryan, Pomona, 1938 and 1939.

St. Lawrence County

Dr. Jay E. Meeker was elected president of the St. Lawrence County Medical Society at the annual meeting at the Crescent Hotel in Ogdensburg on November 22. Dr. Meeker succeeds Dr. S. Pope Brown of Potsdam and presided in the absence of the president. Other officers chosen were:

Dr. David M. Mills, Gouverneur, vice-president, Dr. Samuel W. Close, Gouverneur, secretary-emeritus, Dr. Robert J. Reynolds, Potsdam, secretary, Dr. Lloyd T. McNulty, Potsdam, treasurer, censors, Dr. Paul G. Taddiken, Dr. M. J. Stearns, Ogdensburg, and Dr. F. C. Mason, Massena, delegate to House of Delegates, 1939-40. Dr. W. Grant Cooper, Ogdensburg, alternate, Dr. T. M. Watkins, Potsdam, delegate to district branch, Dr. John E. Free, Ogdensburg, alternate, Dr. C. F. Prairie, Massena.

Following the dinner, Dr. Grant C. Madill, guest speaker, delivered an interesting talk on Socialized Medicine.

A testimonial dinner was tendered Dr. Close at the St. Lawrence Inn at Gouverneur on December 4 in honor of his fifty-one years of service as secretary of the

society At the annual meeting he was made secretary emeritus for life

Schenectady County

At the Annual Meeting of the Schenectady County Medical Society at the Mohawk Golf Club on December 8, the following officers were elected president, John R Schermerhorn, vice-president, Frank L Sullivan, secretary, Joseph H Naumoff, treasurer, Charles E Wiedeman Board of censors, Albert S Fay, Arnaldo A Samorini, E MacDonald Stanton, delegate to the state convention, Frank L Sullivan, alternate, Harry E Reynolds, delegate to the Fourth District Branch, Charles F Rourke, alternate, Isaac Shapiro Representatives to board of managers of Ellis Hospital, A B Van Vranken, Ex-President, J H Cornell, County Soc at Large, A Grussner, Staff—*Reported by Joseph H Naumoff, Secretary*

Steuben County

Dr D Roger Haggerty of Arkport was elected president of the Steuben County Medical Society, succeeding Dr A E Richmond of Wayland, as the Society held its annual meeting in Bath on November 8

Corning physicians were named to the two other executive offices Dr Richard A O'Brien is the new vice-president, replacing Dr Haggerty who moved up to the presidency Re-elected secretary-treasurer was Dr R J Shafer

Dr H B Smith, also of Corning, is again delegate to the State Society, and as alternate, Dr Guy M Parkhurst of Bath was chosen

The Board of Censors was re-elected They are Dr M A Place, Hornell, Dr J J Sanford, Bath, Dr L A Thomas, Painted Post, Dr Stuart H Bean, Addison, Dr E P Smith, Cohocton

Two Syracuse men, Dr Springer and Dr Hyde, presented medical papers

Sullivan County

The following members were elected to office in the Medical Society of Sullivan County at the annual meeting on October

17 president, Harry Golembe, Liberty, vice-president, Ralph S Breakey, Monticello, secy-treas, Deming S Payne, Liberty

Board of Censors Deming S Payne (Liberty), Cornelius Duggan (Bethel), Jacob Kornblum (Monticello), Louis Launer (Liberty), J M Rosenthal (Monticello), and J Stanley Woolley (Liberty)

Compensation Committee Ralph S Breakey, Monticello, and Harry Jacobs, Hurleyville

Alternates Harry Golembe, Liberty, and George Seiken, Liberty, delegate to the State Society Victor G Bourke, Livingston Manor, alternate to the State Society Deming S Payne, Liberty

A physician whose simple mode of life and office fees of fifty cents a visit led to a popular belief that he was a poor and humble country practitioner was recently revealed to have left an estate of more than a quarter of a million dollars An appraisal of the estate of Dr Frederick A McWilliams, of Monticello, who died in August, aged eighty-seven, was filed with Surrogate George L Cooke by Roy C Johnston, Sullivan County Treasurer

Dr McWilliams practiced in Monticello for sixty years He maintained a modest two-room office in the Masonic Building, near the center of the town, and lived in a small apartment behind his office He customarily ate in a lunch wagon next door and although he abandoned his night practice ten years ago, he made perhaps a half dozen calls a day and treated ten or twelve office patients each afternoon

Dr McWilliams' property previously had been assessed at \$1,469, but the list filed included stocks and bonds amounting to \$140,477 73, mortgages, notes, cash, and insurance, \$112,401 02, and miscellaneous accounts totaling \$2,512 He was one of the wealthiest men in Sullivan County

Tioga County

These officers were elected at the annual meeting of the Medical Society of the County of Tioga on December 6 president, Corbet S Johnson, Spencer,

vice-president, Charles J V Redding, Owego, secy treasurer, Ivan N Peterson, Owego, alt delegate, Arthur C Hartnagle, Berkshire, censors, Frederick A. Carpenter, Waverly, F Hallett Spencer, Waverly, Edward S Beck, Owego

The term of Dr Moulton as delegate does not expire this year and he thus continues in that office.

Dr G S Carpenter reported that a Post Graduate Course under the direction of Dr John Moorhead of the Columbia Post-Graduate Medical School has been arranged for March and April

Dr Redding, chairman of the program committee, introduced Dr A D Longmuir, assistant director of the Bureau of Pneumonia Control, who addressed the society on "Modern Trends in Pneumonia Treatment." He also showed "New Day," an educational film on pneumonia for lay consumption —*Reported by I N Peterson, M.D., Secretary*

Warren County

The new officers of the Medical Society of the County of Warren are as follows president, Dwight M. Sawyer, Glens Falls, vice-president, Patrick H Huntington, Warrensburg, secy treasurer, Jesse S Parker, Glens Falls, Board of Censors, Herbert A Bartholomew, John E Cunningham, Roger S Mitchell Delegate to State Society, Morris Maslon

The following Committee Chairmen have been appointed by Dr Sawyer for the year legislative, E Burton Probasco, public health, Morris Maslon, public relations, James B Shields, workmen's compensation, Leonard A. Hulsebosch.—*Reported by Jesse S Parker, M.D., Secretary*

Wayne County

The Annual Meeting of the Wayne County Medical Society was held in Lyons, Tuesday, December 6 The following officers were elected for 1939 president, Dr Edward S Platt, 1st vice-president, Dr Charles L. Steyaart, 2nd vice-president, Dr James L Davis, secy and treasurer, Dr James L Davis, censors, Dr M E Carmer, Dr Arthur Besemer, Dr George Allen, delegate, Dr Ralph Sheldon, alternate, Dr Sam Houston

Sherman W Meech, managing director of the Rochester Hospital Service Corporation explained in detail—Hospital Non profit Insurance Plans The subject was of especial interest because the Rochester Corporation has just received a charter to extend its services into seven counties surrounding Rochester Wayne County is included The Society passed a resolution unanimously favoring Non profit Hospital Insurance Plans and a committee is to be appointed to study and report at a next meeting —*Reported by James L Davis, M.D., Secretary*

Wyoming County

The following are the officers of the Wyoming County Medical Society for 1939 president, George G Davis, Arcade, vice president, G Stanley Baker, Castile, secy treas, Oliver T Ghent, Warsaw

Board of Censors Mary T Greene (Castile), Lester H Humphrey (Silver Springs), and M. Jean Wilson (Warsaw)

Delegate to State Convention, Henry S Martin, Warsaw, alternate delegate Richard B Bean, Castile.

OLIN MILLER SAYS:

*From Dixie Dew Drops in the Atlanta Journal
Relayed by A. C. S., Elberton, Ga*

A government bureau may be making a dreadful mistake in trying to purge the American Medical Association. It is messing around with a bunch of boys who know a thing or two about purgatives themselves.—J A M A

Warnings have been sent out by the Food and Drug Administration against the indiscriminate public use of sulfanilamide, cinchophen neo-cinchophen aminopyrine and related drugs and it is announced that drug preparations containing them and marketed and labeled for general public use are, when found in interstate commerce, actionable.

Hospital News

Those Hospital Visitors!

They mean well Their intentions are good But we have all heard that the road to a certain place is paved with good intentions They mean all right, but the result is all wrong They wish the patient well, but leave him worse than before they came Nor is that all They have a tendency, "like bananas and street cars, to come in bunches," remarks Miss Alice L. Price, R N, B S, of Grant Hospital, Chicago, in *Hospital Management* "So," she adds "often patients who are permitted visitors from two to four o'clock in the afternoon will be alone until three-thirty only to find themselves in the midst of a traffic jam of well meaning friends during the last half hour Seldom, if ever, does one visitor leave when another arrives They stay on and on, believing that there is 'always room for one more' until the walls of the room fairly bulge "

It is hard to tell which is the worst, the "Cheery Visitors," the "Saddened, Long-Faced Visitor," the "Complaining Visitor," the "Timid Visitor," the "I've-Had-It-Too Visitor," or the "Curious" or "Nosey Visitor " There is not room here to pass all these pests in review, as they are described in Miss Price's vastly entertaining article, but she places at the head of the parade the "Cheery Visitor," who is "probably not the most sinister, but certainly one of the most annoying " Here she is

"She comes with great long strides head up, chest out, and breathing deeply, her face set in a grimly determined smile She enters the victim's room at the most inopportune times, pointedly ignores the fact that the patient is perched on the bedpan or has just been given a sedative, and goes into action, 'cheering up' the sick She is secretly pleased at the contrast of her own breeziness with the patient's wan listlessness, she fairly screams of robustness and energy She gloatingly asks, 'How are you?' when

what she really means is 'Look, see how strong and healthy *I* am ' She does *all* the talking so the poor, dear patient won't have to exert herself She is simply thrilled at how much *better* the patient looks Why, she's 'practically out of the hospital already,' and how '*lucky* she is to have nothing to do but rest in such a *lovely* room with nurses and interns to wait on her ' Why, being in the hospital is a '*treat*,' she just believes she 'will go out and get herself a cute little germ so *she* can come in for a rest in this very hospital ' She just bets, too, that the patient 'isn't really sick' because she 'looks so well ' And she knows that soon after being dismissed the unfortunate convalescent will be 'as strong and healthy' as *she* is This type of visitor when ready to withdraw makes doubly sure that her visit has not been in vain by repeating, in a manner which underlines each word, the admonition to 'Don't worry about a thing, and never say die ' She then leaves the sick-room, satisfied that her little visit has brightened the day for the wretched woman who 'anyone can see at a glance is not going to recover ' The patient feels too that recovery is doubtful if she has to endure another such visit. The visitor, so obviously rugged and active, has taken with her the small amount of strength the patient did possess "

Next on the nuisance list is the long-faced type, "who shower the patient with sympathy and try their best to make him feel worse than he already does " They halt abruptly on entering the room, and give the patient a glare full of meaning

"They are shocked by the way he looks and tell him so If he insists that he feels pretty good, they shake their heads ominously and remind him that 'Jim felt pretty good too just before *he* died ' They ask in a worried tone if the doctor has been in yet this morning and hadn't

he better be notified? They wouldn't think of staying very long if they had known the real circumstances, they wouldn't have called at all. They do hope the patient will soon be out of the hospital (their tone of voice conveys their skepticism) because hospitals are so gloomy and depressing.

"The nurse who enters the room after this type of visitor has departed may find the patient worriedly counting his own pulse or trying to catch a glimpse of himself in the mirror. He's sure he is suffering a relapse because he suddenly feels so much worse, and he is so very anxious to have his doctor come immediately."

Skipping several other entertaining types, we come to the Curious or "Nosey" Visitor. Their questions come like shots from a machine gun. How did you happen to come to *this* hospital?

'Why is Dr. Green taking care of you instead of Dr. Brown?' Do you trust your doctors and nurses? Why? "How much are you paying? And so on, and so on. Often this Mrs. Probe is really a scandalmonger—the most deadly of all visitor species—and she tries to nose out some choice morsel of poison. For instance:

Mrs. Probe puts on her most friendly manner and her highly confidential tone of voice and pretending to be the very dear friend of that poor lady in 325, will ask for full information regarding her condition, et cetera. She remarks, "Of course, my dear, we both realize that the hokum in the newspapers about 'appendicitis' is all right for the general public, but, as for us, we both know that the real cause of the illness is something more than that." She's long been aware of the fact that dear Susan hasn't been spending *all* her evenings at the library as she claimed. And of course, *she's* had her suspicions for a long while now. Just what *did* the doctors find out? You can be sure she won't breathe it to a soul.

The supervisor informs Mrs. Probe that all information about patients has to be given out by the patient's doctor. Mrs. Probe splutters with anger, and

departs in a cloud of dust, convinced that there is something wrong, or the nurses wouldn't be so noncommittal.

The most virulent type of Mrs. Probe has even gone so far as to offer to pay for knowledge of the hospitalized friend, especially if it promises to be good material for a class A scandal."

But after poking fun at all these pestiferous callers Miss Price has to admit that not all the visitors are like that. In fact:

"There is a kind of visitor who is most welcome to hospital patients. He is as rare as a snowstorm in July but may be found occasionally. He visits patients at a sensible time. He stays only a short while. He talks of things that really interest the patient, and he does not sit on the bed. Hospitals should encourage such a visitor to call again, for his effect on the patient is beneficial and may lead to direct physical improvement."

There is no doubt that the problem of visitors is becoming acute, and like other problems that have presented themselves from time to time, this one will eventually be solved. The solution will likely be found in training hospital visitors rather than in eliminating or further restricting them. If we can make all visitors the type that are an asset instead of a liability, the kind who work with the hospital staff instead of against it, then we do not need to limit their number or their hours of calling.

London's "Emergency Hospital Bed Service"

An important advance in hospital administration has been made in the London area by the opening of the emergency hospital bed service. Here tofore the 8 000 physicians practicing in London have lost much time in telephoning from hospital to hospital in search of a bed for an emergency case. The new service, as described in the *J.A.M.A.* is a central clearing house for all the voluntary hospitals, at which information can at once be obtained.

When a physician has an emergency or acute case which he wants to be admitted he rings up this service and is asked his name and telephone number, the patient's name, age and sex, and the diagnosis. If he states the hospital to which he wishes the patient to be admitted, the service will tell him whether a bed is vacant and if it is will book it for him.

If there is no vacancy he will be asked to state his next preference, and so on until his requirement is met. In the case of certain hospitals which have undertaken to bear the cost of an ambulance, the service will also book this. The service will be open every day from 8 a m to 10 p m, and it is intended to extend it in due course to the twenty-four hours.

By a system of colored disks on an indicator board, the staff members of the service are able to tell at a glance whether a bed is free at a particular hospital for a man, woman, or child or for what particular type of treatment it is available. A preliminary working test showed that there are likely to be sufficient beds available to meet the requirements of physicians, and in most cases admission was obtained for the patient within fifteen minutes.

No charge is made for the service, since the cost is met by King Edward's Hospital Fund for London. It should be noted that the service is for the London voluntary hospitals, which all work as independent units. It is not required for the 36,000 beds of the London municipal hospitals, which are under the single control of the county council and therefore already have a co-ordinated system.

Ethics in Hospital Solicitation

He admits that he dare not sign his name—a manufacturer who supplies items used by hospitals, who writes to *The Modern Hospital* to protest against the practice of some hospitals that ask manufacturers to contribute—under a veiled threat, "or else!" And the editor of the hospital magazine endorses his protest and reports that this "pernicious"

practice "seems to be spreading." Manufacturers and hospital associations "should take a firm stand" against this sort of thing, urges the editor—"a pussy-footing policy will no longer be effective." The anonymous manufacturer signs himself "One Who Would Like to See all Hospital Contacts above Reproach," and his letter reads:

"We are manufacturers of certain items used by hospitals. After you have read this letter, you will understand, and we trust, appreciate why it is that we write you incognito, for while we have the full courage of our convictions, after all, we get our bread and butter from hospitals. While this letter criticizes the action of some hospitals, of course it doesn't criticize all of them.

"The solicitation of contributions by hospitals from companies which are serving them with merchandise is one of the greatest evils existing in the hospital field today. We can understand thoroughly how patients, who have received excellent treatment, would gladly contribute to requests for funds. We think solicitations from people like that are fully warranted. Those living in the territory served by an important hospital, who have been or could be patients of that hospital at any time, could be asked with dignity for assistance in maintaining the proper activities of hospitals, which have been so affected by present and past economic conditions.

"But, any hospital superintendent who approaches a manufacturer who furnishes the hospital with merchandise with the implication, 'You had better come through here, or else there's a chance you won't get a continuation of our patronage,' is doing his own hospital and all hospitals a great injustice. Any company that's in business has got to make a profit to stay in business. If we who furnish hospitals are obliged day after day to make contributions of this sort, there is just one place that they are ultimately going to come from, an increased price to the hospital consumer.

"This situation has existed so long partly because of the fear on the part

of the manufacturer that his business would be greatly injured if it were known that he publicly expressed disapproval of such procedure. We are frank to admit that we cannot initiate an active measure of any sort against such procedure, but certainly you, as the editor of the leading hospital publication of the country, must recognize that what we are telling you is the truth'

Injection Risks

A patient in a German hospital, suffering from a serious case of pneumonia, was given an injection of luminal into the thigh, developed gas gangrene, and died. The assumption of the doctors who discuss it in a Munich medical journal (*Munch Med Wschr* 85 125 (1938)) is that gas gangrene began at the site of injection and quickly caused death.

The interesting point is that typical *Cl welchii* were found in the 70 per cent alcohol in which the syringe was kept. As related in the *British Medical Journal*, an inquiry at many hospitals showed that in Germany syringes and needles are kept in alcohol as a routine in the wards, being boiled between successive injections or sometimes merely washed with alcohol.

As this method has the authority of a number of text books and was taught in many universities, the medical man was finally exculpated. It is emphasized in the report that Koch as long ago as 1881 showed that anthrax spores resist alcohol, and that Wankle in 1926 traced a death from gas-gangrene to *Cl welchii* spores which were present in the alcohol in which the syringe had been stored. Dalrymple-Champneys and Garrod and Keynes have pointed out the danger of trusting to alcohol for disinfection, in certain conditions staphylococci may survive even for several hours, and spores have been found in material which had been immersed in spirit for twenty years. C. G. Coulthard and G. Sykes, in a review of the literature recording infection by spore-bearing bacteria, stress the failure of ordinary alcohol to kill spores.

They found that by adding 1 per cent of various acids or alkali, or a cresol derivative, the destructive power for spores was considerably increased.

Jungmichel and his colleagues state that the risk of gas-gangrene must be small, for though many deaths from gas gangrene or tetanus following hypodermic injection are recorded, cases of this kind are very rare in the myriads of injections carried out all over the world. They mention that to every experienced hospital superintendent the occurrence of local sepsis after injection is a well known phenomenon. They further conclude that since the spores of *Cl welchii* occur in all garden soil and dust they must be injected very often by patients or by doctors in private practice away from the sterilization resources of a big hospital, and that the spores do not germinate unless the condition of the tissue favors this.

They therefore warn doctors against repeated injections at the same spot, or injection into the buttock at a place where the muscle is subject to injury in ordinary life.

The question then arises, what should replace the condemned practice of storing syringes and needles in alcohol? The ideal is to autoclave every syringe and needle after every injection—an ideal unattainable in practice. The authors suggest that in hospitals syringes and needles should be autoclaved or sterilized by dry heat and each one stored, until used, in a dust proof package. For the doctor in practice the problem is a difficult one, ordinary boiling in water is not sufficient, and the authors finally recommend boiling for ten or fifteen minutes in water containing 3 per cent soda.

Most bacteriologists will agree with the general argument of the German writers, and will advise the prudent practitioner who consults them to boil the syringe and needle for a few minutes in water containing a little sodium bicarbonate, sodium hydroxide, or lysol, and thoroughly to wash the syringe through with sterile water before drawing up the solution to be injected.

Newsy Notes

The 16th annual "hundred-dollar-a-plate dinner for the benefit of Israel Zion Hospital in December in the Hotel St George realized about \$40,000, according to David N Katz, chairman of the event. Close to 2,000 persons, including jurists, industrialists, business and professional men, were among those present.

The money raised will go toward furnishing the new wing of the institution at 49th St and 10th Ave, Brooklyn. The eight-story building, when opened, will add some 250 beds to the facilities of the hospital, which at the present time takes care of between 460 and 480 patients.

X-ray therapy facilities, creating a Dutchess County Tumor clinic, donated by Herrman A Schatz in memory of the late Dr James E Neighbors, were dedicated formally on December 9 with the unveiling of a tablet at Vassar Brothers' Hospital in Poughkeepsie by Dr Scott Lord Smith. Inscribed on the tablet is "A memorial to Dr James Edward Neighbors who was associated with Vassar Brothers' Hospital from July 1, 1920, to September 13, 1938. By one who loved him."

Edward Benedict Cobb, retired New York and Washington lawyer, who died at Pittsfield, Mass., in November at the age of eighty-nine, left \$100,000 to the Tarrytown Hospital Association under the terms of his will, filed at Washington.

A campaign has been started to reopen St Marks Hospital, at Eleventh Street and Second Avenue, New York City as a free maternity center and baby health station.

POLAND POINTS THE WAY

Smallpox has become an extinct disease in Poland, where the law on compulsory vaccination and revaccination is strictly enforced. Complications of vaccination are rare, and no cases of

Improvements

A movement is under way to secure a Veterans' Facility Hospital for the Glens Falls area. The Federal Government has assured those fostering the movement that such a hospital will be built if the need can be proved.

Modernized and enlarged facilities are expected to be ready at the House of St Giles the Cripple in Brooklyn by April 1, it is announced by Juan C. Butts, general manager of the administrative staff.

Of the \$25,000,000 worth of public buildings to be erected in a program of state projects now being planned, Utica State Hospital will receive \$206,000, according to a Utica paper. J B Fordham, steward at the Utica State Hospital, when informed of the appropriation, said his advice was that the hospital would receive an allotment of \$196,000, including \$120,000 for a shop building 50 by 300 feet to contain the print shop and an addition to the cold storage plant at \$76,000.

The Board of Zoning Appeals of the Town of Hempstead has granted the application of the board of trustees of Mercy Hospital for the erection of a new building on the east side of Mill Road, south of the Southern State Parkway, in South Hempstead. The trustees plan to erect a modern four-story hospital building on the site.

Construction and maintenance of a new tuberculosis sanatorium by Orange County is urged by Newburgh's City Council in a resolution adopted at the suggestion of Dr Anthony J Manzella, city health officer.

postvaccinal encephalitis have so far been reported in Poland. In many towns where immunization against diphtheria is also compulsory, protection against the two diseases is carried out at the same time.

LORFENZ J. BROSNAN Esq

Council Medical Society of the State of New York

Practice of Medicine by Chiropractor

A DECISION rendered a few weeks ago by one of the magistrates of the City of New York in a proceeding brought charging violations of the Medical Practice Act is of considerable interest.¹

The Attorney General acting on behalf of the People of the State of New York charged the defendant with the crimes of having unlawfully practiced medicine and having unlawfully designated himself as a practitioner of medicine.

The matter came up before the magistrate upon an application on behalf of the defendant to dismiss the complaint on the grounds that the facts charged in the complaint would affirmatively show that the defendant was not guilty of the crimes charged.

In order to understand the ruling made by the Court it is necessary to trace in some detail the allegations of the complaint. It seems that the defendant maintained an office, in the windows of which the title "chiropractor" was displayed. Said title also appeared with his name on his letter box. Certificates were hung in his office issued to him by the Palmer School of Chiropractic, representing him to be a D.C. and a Doctor of Chiropractic.

Similarly he was also listed in the telephone directory as a chiropractor.

It seems that three investigators were sent to the office of the defendant for the purpose of investigating his activities. It was charged that when the first investigator visited the doctor she complained of pains in her back and frequent headaches, and was told by the defendant that he doesn't practice medicine, diagnose, or prescribe medicines but all he did was to give chiropractic treatments and adjustments. However he applied an

instrument known as a neurocalometer to her back and jerked her head from side to side and manipulated her spine and made arrangements for a series of treatments.

During the course of said treatments the defendant was told of the investigator's complaints, including nausea and vomiting and he told her that he did not believe the nauseousness was caused by his treatment that she must have upset her stomach, that the pain in her back would right itself, and that a preparation which she was using could do no harm. She also asked him about a tumor on her back and after examining it he told her it was not the cause of her backaches and headaches. She also complained to him of a painful injury to her foot and a swollen ankle and he then pressed along her spine and inquired as to whether her foot felt any better to which she answered in the affirmative.

According to the complaint a second investigator called upon the defendant with complaints of severe headaches, a clogged nose, and sleepless nights because of difficulty in breathing and because of pains 'from her nose through her eyes up to the top of her head.'

The chiropractor inquired concerning possible connections between her headaches and her menstrual periods and in the course of his conversation with her he told her not to worry and that she would leave his place minus the headache. He likewise applied the neurocalometer against her back and manipulated her spine and on a subsequent occasion he explained that her pain came from nervous pressure. He refused to suggest a diet for her but advised other forms of relief and told her to patiently continue with his treatments.

A third investigator went to him with complaints of pains in her back and was told that he would not diagnose her case but would give her adjustments because

¹ People vs. Zinke

Decided November 18 1938.

it was against the law to tell her what was wrong with her, or to tell her that he could help her. She told him that she had pains in her back and wanted him to help her and he likewise administered to her a treatment which included jerking her head from side to side and manipulations of her spine with his hands. A fee was charged for three treatments and on a later visit the investigator told the defendant that she had been quite sick and was assured by him that she must have patience and that everything "would work out all right."

She also complained to the chiropractor on one occasion of the fact that she was suffering from bleeding hemorrhoids and that she expected her menstrual period any day and asked if it would be all right to be treated under such circumstances. She was told that on the contrary his treatment would help her and as to clearing up the hemorrhoids she should "just wait and see." A stomach complaint was also called to the attention of the chiropractor by the third investigator and she was told that it might be gas but that she should not worry about it as he was sure she would be all right.

The foregoing summarizes the salient features of the complaint. The defendant claimed that from the complaint it did not appear that he had held himself out as able to diagnose, treat, operate, or prescribe for any human disease, pain, injury, deformity, or physical condition. He contended that the charges actually negated the violation charged since it appeared from the charges that he had informed the investigators that he didn't practice medicine and that he did not diagnose cases but would just give adjustments. The court, however, ruled that the complaint sufficiently charged the defendant with the crimes of illegally practicing medicine so that he should stand trial for the offenses charged. In so ruling the Court said in the opinion:

"The Court finds that there was directly and by inference a holding out by defendant that he was able to perform one or more of the prohibited acts. He displayed certificates bearing his name as a "Doctor of Chiropractic" and signs

bearing his name as a "chiropractor" and he listed himself as a chiropractor in the telephone directories. These signs and certificates are in themselves presumptive evidence of a holding out under the statutory presumption above set forth—the titles "doctor" and "chiropractor" carry with them definite implications that the possessor of those titles is able to treat bodily conditions.

"The whole set up of defendant's office, attendant, dressing rooms and split-back robes, neurolomometer, and articulated table, all have a direct bearing on the holding out—they consisted of equipment of one who uses same as preliminary to and in the actual treatment of physical conditions. One of the investigators inquired of defendant whether she had sinus and he told her that she should not worry and she would leave his place "minus" the headache and she should continue with his treatments and have patience—certainly thereby he represented he was able to treat her conditions. He told another investigator that his treatment would not harm her menstrual condition but would help her and as to her hemorrhoid condition she should just wait and see, and that she should not worry, for he was sure she would be all right—one making such statements must be deemed to have held himself out as being able to make that person "all right" by his treatments.

"Aside from the direct holding out, there is an implied holding out from the acts performed. From the taking of the histories of the patients and his subsequent treatments and the acceptance of compensation therefor, there is an inference of a holding out. The Court of Appeals has held, in a case involving the practice of chiropractic, that in offering to treat a person, the practitioner holds himself out as qualified to give treatment.

"In view of the statements made by defendant and his acts, all constituting a holding out, any negation of a holding out by defendant cannot be viewed seriously. If any such negation were considered controlling in the circumstances here existent, the medical regulations could readily be nullified and rendered a dead letter. To this Court, the negation is but a false pretense, for defendant proceeded to perform the very acts which he pretended he did not perform. And defendant's use of the terms "chiropractic treatment" and "adjustments" is nothing more than an effort to evade the statute and the Court will not be taken in thereby (*Kuechler vs Voigman*, 192 N W 1015). In that case, the Supreme Court of Wisconsin, after holding that the defendant-chiropractor undertook to diagnose and treat, said "Diagnosis is ordinarily assumed and

performed by licensed medical or osteopathic physicians. But it may be assumed by others, and it is held that the practice of chiropractic is the practice of medicine. And the fact that chiropractors abstain from the use of words like "diagnosis," "treatment," or "disease" is immaterial. What they hold themselves out to do and what they do is to treat disease and the substitution of words like "analysis," "palpation" and "adjustment" does not change the nature of their act.'

Defendant diagnosed. His history taking examination with the use of a neurocalometer and his statements as to the causes of conditions of the investigators show that he had made a determination which he deemed sufficient for the purposes of treatment. The term diagnosis is derived from the Greek prefix *dia* meaning between and *gignoskein* meaning to discern. It is, in modern terminology a 'sizing up' or a comprehending of the physical or mental status of a patient. It is the conclusion itself rather than the procedures upon which the conclusion is based which constitutes a diagnosis *per se*. No particular language need be used and no disease need be mentioned, for the diagnostician may make or draw his conclusion in his own way.

Defendant undertook and offered to treat. The definition of the practice of medicine states that the treatment may be by any means or method. Defendant's method was manipulation of the spine—what is known as the practice of chiropractic. In 11 Corpus Juris 758 chiropractic is defined as 'A system of healing that treats disease by manipulation of the spinal column.' It is said in *Brown vs. Skayne* 243 N.Y. 176 183 'We readily see therefore that the chiropractic doctor holds himself out to treat and cure sickness and disease by the readjustment of the spinal column and the proper alignment of the vertebrae.'

'This court is not concerned on defendant's motion to dismiss with whether chiropractic treatments are beneficial or injurious. The only question is whether the facts stated in the complaint show that defendant violated the law. The proof at the trial will necessarily be confined to the particular acts which it is claimed constitute a violation. But in view of contentions of defendant as to the purpose of the statutes regulating the practice of medicine this Court desires to emphasize that the legislature of this State has in its wisdom recognized the necessity of protecting the people by prohibiting those not licensed from meddling with their health. Especially is that important as to female sufferers who enter the office of an unlicensed practitioner where they are required to partly

disrobe and then submit to various forms of bodily manipulations.'

X-Ray Treatment of Psoriasis

A man about forty years of age consulted a physician who specialized in dermatology with respect to a condition of psoriasis from which he had been suffering for approximately eighteen years. He told the doctor that he had used various types of medication in the treatment of the condition and that when it had become severe he had used chrysarobin on his right arm. The examination showed an irritation due to chrysarobin on the right arm and that the patient was suffering from psoriasis all over his body manifested by whitish, raised lesions covered by scales.

The doctor administered a series of x ray treatments to the patient which were continued from time to time over a period of about five weeks. These treatments were administered to various parts of the body but at no time was any x-ray therapy given to the right arm where chrysarobin had been applied. After the x-ray treatments, the patient developed exfoliative dermatitis on his back, flanks, and right shoulder. The defendant undertook to treat the condition on two occasions following the last of which, although he was instructed to return, he never again appeared for treatment. It was ascertained, thereafter, that the patient was hospitalized for a period of about six weeks for the purpose of undergoing treatment for exfoliative dermatitis.

A malpractice action was instituted against the physician in which the charge was made that the defendant had negligently administered the x ray treatment to the patient causing the exfoliative dermatitis to develop.

The case came on for trial before the Court and a jury and the plaintiff claimed that the defendant had improperly superimposed x ray therapy upon a region previously treated with chrysarobin and that as a result of such alleged improper treatment exfoliative dermatitis developed. The defendant denied the claim

and asserted that he had never applied x-ray therapy to the portion of the body in question. The issues in the case were submitted to the jury and a verdict in favor of the defendant was returned thereby exonerating him of all charges of malpractice.

Removal of Scar by Plastic Surgery

An ex-soldier, thirty-six years of age, consulted a surgeon who specialized in plastic surgery with respect to the removal of two scars. The doctor found a small scar below his lower eye-lid and a scar $7\frac{1}{2}$ cm long by $4\frac{1}{2}$ cm wide, flat and introverted, on his neck at the junction of the lower mandible.

The doctor had the patient enter a hospital where, under a local anesthesia, he excised the neck scar and drew the edges together and with silk paraffin sutured the edges together. The patient remained in the hospital ten days and the

surgeon attended him during that time following which at his office he excised the eye-lid scar, drew the edges together, and sutured them. He saw the patient from time to time over the following period of three months and at the end of that time the scars were healed and nothing was present at the site of the scars except two fine lines.

A malpractice action was brought against the doctor in which the charge was made that by reason of the negligent manner in which the operations had been performed, the plaintiff was caused to suffer severe pains throughout his body and limbs and to suffer from nervousness, dizziness, and weakness. The case came on for trial before a Court and jury and the plaintiff failed to establish that in any respect the defendant had failed to follow proper practice in the treatment rendered. At the conclusion of the testimony on behalf of the plaintiff, the case was dismissed on the motion of the attorney for the defendant.

THE LONG-WHISKERED DOCTOR OF THE STORY BOOKS

An English journal which calls itself "The Economist" ends a short article on "Doctors and the Public" with,

"The doctors will enjoy the respect of the public to precisely the same degree that they do not behave like a commercial vested interest."

It is said the whole world loves a lover, but apparently if any such regard is held for the doctor in this country as in Great Britain, it is a very special type of doctor, replies the *Journal of the Indiana State Medical Association*. He is the country or city practitioner with a full beard who answers all calls day and night, keeps no books, sends no bills, dies at fifty-five of a coronary occlusion, and leaves to his wife and children a doubtful future.

A physician has no right, it seems, to watch after his own interests and make himself an income sufficient to take care of his overhead and have a little left over for life insurance. Strangely, no patient, even if he doesn't intend to pay, wants to have a doctor drive up to his place in a jalopy car. His doctor must maintain a good looking car and a properly furnished

office. However, if such is the appearance of prosperity, the patient figures that the doctor must not need the money and worries not when he pays.

The public has taken to itself the picture of the self-sacrificing, charitable physician and does not care to lose it. This is proper and we as physicians should do our best to maintain this picture of charitable self-sacrifice, but we have a right and a duty to be practical business men as well.

Recently a physician told of meeting a nurse who had been with him on an obstetrical case many months previously. She asked, "Doctor, did you ever get any pay for that case I helped you with last year?"

"No!" was his reply. "I haven't heard from them since. Did you get your money?"

"No, doctor, I didn't either," she answered. "And I heard later that the husband was worried as to whether you got home all right. It seems that while we were in the house delivering the baby, he was outside siphoning the gasoline out of your car!"

Across the Desk

"Syphilitic Scars of the Spirit"

THE success or failure of a life may hang on the attitude of the doctor at the first visit of a patient with syphilis, declared Dr Austin W Cheever, of the Harvard Medical School, in a paper with the above title read at the annual meeting of the Massachusetts Medical Society. And that is a thousand times more important than the mere success of the medical procedure. The man or woman is more than the disease, and the treatment should be more than "just what can be pressed through a needle into a vein."

One attitude by the doctor, and the patient is encouraged to face life with hope and win the battle, another attitude, and he or she jumps in the river. "By all odds, the most important contact between patient and physician is the first one," declares Dr Cheever, and "in a busy practitioner's office, regardless of the dozen patients in the waiting room, the one with suspected syphilis must be considered that day's emergency." Failure may ruin a life.

How Not to Do It

Take the brutal remark of a doctor to a young woman whose infection turned out to be a wedding present from her husband. The doctor, however, made no effort to find how she came by it. He told her the treatment would cost a thousand dollars, and when she said she could not possibly afford it, he retorted:

"Go out on the street and earn the money the same way you got the disease!"

The result was that she fled from his office, and it was three months before she could muster the courage to go to another doctor. By good fortune it was Dr Cheever. But three months had been lost, and an extremely disfiguring rash had developed.

The golden opportunity of the first consultation had been mishandled.

At the first visit, says Dr Cheever

"One must explain in simple, straightforward language what is ahead of the patient that the recurrences, disappointments, chances of infection of the mate, danger of having congenital syphilitic children, and serious or even tragic late complications, such as actually used to occur not rarely under the old mercury regime, can all be controlled now, provided adequate treatment is given and the patient does his part by co-operating and taking treatment properly. Even the seemingly worst situations, such as a young couple with early syphilis and the girl pregnant, need cause but little alarm, for if the case is properly handled the probability is that the parents will be cured and the fetus saved."

Danger of Explosions

An emotional explosion may occur when the patient learns the diagnosis, and threats of suicide are sometimes uttered—but seldom carried out. Another reaction, "What's the use? Why try to be good any more?" may lead to moral and physical disaster. Has the physician no duty in such cases? Dr Cheever relates an instance that came under his own observation.

"A very highstrung but likable boy had been coming to the hospital clinic for several years for treatment of congenital syphilis. When he became a college freshman he happened by accident to see the diagnosis on his record. He said nothing to anyone of his discovery, nor did he give a hint that he was upset by it, but went immediately to a ticket office of one of the air lines and bought a ticket home to a far western state.

"Very fortunately he talked in his sleep. His room mate heard him and found out what the boy planned to do, namely to go home and kill his father. The room mate

tried to argue him out of it, and when this did not work tried to get the air line to cancel the passage. They refused, thinking it was some college prank. There was only one course left for the roommate, and he took it.

"Both boys went to the airport, there the room-mate staged such a row that the pair were arrested, and naturally the passage was canceled. Later an understanding doctor took this boy in hand and explained the entire case to him so carefully that he was able to realize just how hot-headed and foolish his previous attitude had been."

Making the Flesh Creep

Then, too, the popular mind is filled with wrong ideas and old prejudices, handed down from bygone years of ignorance. Grandma's "doctor book" reeks with lurid tales of the horrors of syphilis as they occurred seventy-five years ago, when cases were recognized only by the ravages of the disease, and when a victim happens to open it at that page, the hair rises, shivers chase up and down the spine, and the flesh creeps. Even patients waiting in the clinic seem to delight in exchanging remarks that would give anyone the horrors.

Years ago, Dr. Cheever recalls, a young woman came to the clinic with secondary syphilis, stating that there was a history of just one contact, her fiancé. Examination of the fiancé "revealed an accidental syphilis with a trivial primary lesion of the lip and a rash so faint that its significance had never dawned on him." Both remained under treatment and subsequent semiannual examination six or seven years, when it was noticed that the woman was losing weight rapidly. Questioning revealed that she had heard people say that syphilitics should never marry. She was encouraged to marry at once, her weight returned to normal, and she seemed to grow ten years younger. "I believe," says Dr. Cheever, "we had failed dismally on our first contact with that patient."

A Word to Employers

Another widespread error is the prejudice against employing those who have had syphilis. "A known syphilitic under treatment is of no possible danger to his fellow man," says Dr. Cheever, and he believes (and hopes) that many such are employed in the Massachusetts General Hospital and other hospitals, for it is now the accepted policy to try to find them employment. He adds:

"How unfair is the refusal of a housewife to give work to a nursemaid with congenital syphilis, whose infectiousness was spontaneously cleared up perhaps twenty years ago while she was still an infant! Yet do we do all we can to explain such circumstances to the layman?"

"A case in point, occurring about two years ago, remains in my memory, for though the girl was not badly marked, any third-year student would have recognized her Hutchinsonian teeth and hazy corneas.

"The prospective employer had a fit of terror and even threatened fumigation of the house after the first few minutes of the interview. The family physician seems to have agreed with the employer, her pediatricist tried to make her see the light, but to no avail. The young woman has since proved her lack of infectiousness by marrying and having a perfectly healthy baby."

One Guess Allowed

The impressive statement that syphilis could be stamped out in this country by an expanded public health program costing \$25,000,000 a year for ten years is made in a pamphlet called "Behind the Syphilis Campaign." In contrast, it now costs \$41,000,000 a year to care for the victims, or more than is needed to stamp it out.

But will Congress, strewing its billions here and there, like an inebriated mariner, appropriate the \$25,000,000 to do it?

You guessed right the first time

REVIEWED

Essentials of Psychiatry. By George W. Henry. Third edition. Octavo of 465 pages. Baltimore, Williams & Wilkins Company 1938. Cloth, \$5.00

This book covers the essentials of psychiatry in a simple, comprehensive manner that should appeal to either a student or practitioner. In this third edition there is considerable new material which brings it up to date. Personality development and disorders of the personality pave the way for the study of the more specific

mental reactions, and the actual case records that are exhibited serve to illustrate the practical application of psychiatric principles. The author's extensive experience in hospital practice enables him to cite many cases that show the constant close relationship of psychiatry and general medicine. Other outstanding chapters are those on treatment, nursing, psychopathology of the normal, disorders of childhood, and psychiatry in general hospital practice. The subject is well

rounded out, and the book should be a distinct help to the student and practitioner

A E SOPER

A Textbook of Clinical Pathology. Edited by Roy R. Kracke. Octavo of 567 pages, illustrated. Baltimore, William Wood & Company, 1938. Cloth, \$6 00

This textbook of clinical pathology is written by a group of experts, teachers, and practitioners of laboratory medicine, and each a specialist in the topic under discussion. The text is clearly written and profusely illustrated. It correlates the laboratory findings with the diseased processes, and should be of great aid to practicing physicians and students in the diagnosis and treatment of disease.

EDWARD H. NIDISH

Materia Medica, Pharmacology, Therapeutics and Prescription Writing for Students and Practitioners. By Walter A. Bastedo, M.D. Fourth edition. Octavo of 778 pages, illustrated. Philadelphia, W. B. Saunders Co., 1937. Cloth, \$6 50

As a standard textbook for students and a reference book for practitioners the author of this work, now in its fourth edition, is to be complimented for its excellence. Since its first edition, it has ranked foremost in books on this subject because of Dr. Bastedo's rich experience in the fields of pharmacy, medicine, and as a teacher of pharmacology. The splendid way in which the various topics are presented adds much to its practical value as a reference book. The entire text has been revised and many of the newer drugs have been included among which are coramine, cyclopropane, dinitrophenol, mandelic acid, metrasol, pentnucleotide, progestimine, protamine-insulin and its zinc compounds, sulfanilamide (prontylin), and other remedies. The toxic effects of the more recent drugs are also included such as aminopyrine, cinchophen, dinitrophenol, and others. The chapter on prescription writing is not as complete as it might be and could be improved upon for the benefit of those who

lack fundamental training in pharmaceuticals which is sadly omitted in the curriculums of most of our medical schools. It would be impossible to comment upon the many drugs considered in this work but outstanding is that of digitalis in connection with which are many electrocardiographic illustrations showing the effect of overdosage, heart block, extrasystoles and auricular flutter, auricular fibrillation, and other disturbances causing cardiac dysfunction. This volume, written in the usual clear, simple style of the author, is highly recommended to those who desire an authoritative work on this subject.

F. SCHROEDER

The Therapeutic Problem in Bowel Obstructions. A Physiological and Clinical Consideration. By Owen H. Wangersteen, M.D. Quarto of 360 pages, illustrated. Springfield, Charles C. Thomas, 1937. Cloth, \$6 00

It is easy to see why the first part of this book received the Gross Prize from the Philadelphia Academy of Surgery. It is not only interesting to read, but is one of the most important books published in a long time. It summarizes the enormous amount of experimental work on intestinal obstruction done by the author and his associates, and describes in detail the procedures necessary to insure a lower mortality in the treatment of this so usually fatal condition.

Part I is largely devoted to reports of researches indicating that the two important factors in obstruction are the effects of distention on the viability of the bowel and the loss of fluids due to vomiting, failure of absorption and blood loss. Criteria for recognition of obstruction are described, and treatment—by saline, blood transfusion, decompression by duodenal tube and operation—is dealt with in detail. Part II takes up general considerations of diagnosis and treatment of bowel obstructions, covering every subject in clear and minute detail. Part III includes a discussion of each of the many causes of obstruction and the special

diagnostic and therapeutic measures indicated in each type.

This book is an extremely valuable reference work, and should be owned and frequently referred to by the general practitioner as well as by the specialist

A F R ANDRESEN

A Diabetic Manual for the Mutual Use of Doctor and Patient. By Elliott P Joslin M D. Sixth edition. Octavo of 210 pages illustrated. Philadelphia: Lea & Febiger, 1937. Cloth \$3.00

Again we welcome an edition, the sixth, of this most popular volume on diabetes. Meant for the doctor as well as the patient, this little book gives an excellent bird's-eye view of the disease and its treatment in simple intelligible form. It breathes into the patient, by its dramatic handling of cold statistics and its numerous diabetic parables, a sense of encouragement to effort and a reassurance that all will be well if he but "plays ball" with his doctor.

Questions and answers typical of those between patient and physician are presented. "Diabetic arithmetic" is explained. Diet, hygiene, urinalysis, insulin administration, and diabetic complications are well presented for the patient's use. Prognosis, etiological factors, and preventive measures are duly covered. Twenty pages are devoted to tables of composition of common foods.

GEORGE E ANDERSON

Manual of Human Dissection. By Edwin M Shearer Ph.D. Quarto of 321 pages illustrated. Philadelphia, P. Blakiston's Son and Company 1937. Cloth, \$4.25

Dr Shearer has achieved an unusual clarity in his conveniently sized *Manual of Human Dissection*. The work is ably brief. It provides at the same time a coordinated view of areas to be studied and a guide to the laying bare of individual structures. The book is sturdy and has a washable binding. The print is of restful size. A helpful diagrammatic clarity characterizes the ample illustrations. Dr Shearer has removed the need for struggling with his subject matter because

of his decisive writing and splendid teaching ability.

CARLETON CAMPBELL

A Practice of Orthopaedic Surgery. By T P McMurray, M B. Octavo of 471 pages illustrated. Baltimore: William Wood & Company, 1937. Cloth, \$5.00

Dr McMurray describes orthopedic surgery as the surgery of the framework of the body—a rather new and expressive thought. He comments on the difficulty of outlining the scope of this specialty, but reduced to its simplest terms it is, says the author, the surgery "concerned with injury, deformity, or disease of the spine and extremities." He is conservative in his therapy, urging that "extensive operations be avoided as far as possible." His broad concept of medicine is the key note of the volume. The gentle approach of the physician to his patient is also emphasized, a theme which even in this day and age of practical psychology bears repetition.

A chapter on splints clearly demonstrates the depth of sentiment and loyalty which he has nurtured for the memory of Owen Thomas and Sir Robert Jones. The principles are sound, and the brace construction simple, which, after all is what one wants.

The problem of adhesions about joints is well presented, and the note of warning sounded again against "free manipulation of the stiffened elbow or finger." This chapter is replete with aphorisms quite like the one quoted.

Five chapters are devoted to tuberculous arthritis, with the orthodox plea for obtaining ankylosis to insure a cure. This lesion of the bones is fast disappearing from clinics in this country, probably due to our meticulous system of regulation of the milk supply, but abroad it is still a problem of magnitude. The arthritides, rheumatoid, and chronic hypertrophic arthritis, are appraised briefly. Spinal conditions are presented in an inviting and understandable manner.

The chapters on obstetrical paralysis, poliomyelitis, and congenital dislocation

of the hip are well-worth reading. A rather clever manipulative measure for the relief of pain in tennis elbow is described under affections of the muscles and tendons. Rickets, Paget's disease, osteomyelitis, and bone tumors are also discussed.

The scope of this volume is broad, the text full of splendidly condensed fact, and the treatment practical, and in the main, simple. This is a very good book by a disciple of the Dean of English Orthopedists, Sir Robert Jones, and should be a valuable adjunct to any library.

DONALD E MCKENNA

A Monograph on Veins. By Kenneth J Franklin, M D. Octavo of 410 pages, illustrated. Springfield, Charles C Thomas, 1937. Cloth, \$6 00.

This excellent monograph presents a comprehensive survey of the heretofore inadequately summarized knowledge of the anatomy, physiology, and pathology of the veins. The information given is most complete, yet the style of presentation is simple and readable. This book is recommended to all those interested in the veins, whether they be anatomists, physiologists, or clinicians.

An excellent bibliography is given.

G. B RAY

Medico-Legal Aspects of the Ruxton Case. By John Glaister, M D, and James C Brash, M D. Quarto of 284 pages, illustrated. Baltimore, William Wood & Company, 1937. Cloth, \$8 00.

This book is unique in medicolegal history. We have never read nor seen murder handled with such meticulous care. Every piece of human remains, every article of clothing, in fact any material that might shed light on the reconstruction of the crime was used to the utmost. That the dead can be made to speak and speak the truth is certainly well illustrated. "Dead men are made to tell tales." It is a book that is of peculiar interest to the coroners' physicians, medical examiners, police prosecutors, and lawyers, illustrating the modern methods

and application of newer knowledge to the detection of crime. The book is profusely illustrated by finely detailed pictures. There is an excellent account of reconstruction of human remains, the careful preservation of evidence, how sex, age, and stature of bodies may be determined, and methods used in establishing the identity of the bodies by fingerprints, dental evidence, and other special markings.

It gives in detail what advantage may be obtained from blood examination by application of serologic precipitation tests and how evidence is best presented at murder trials. We are sure that after reading this remarkable book, those immediately interested in forensic medicine cannot help but be stimulated by this to more careful work and better effort.

M. EDWARD MARTEN

Modern Dietary Treatment. By Margery Abrahams, M.A., and Elsie M Widdowson, Ph D. Duodecimo of 328 pages. Baltimore, William Wood and Company, 1937. Cloth, \$3 25.

This book written by practicing dietitians presents the subject of nutrition in health and disease in simple easy English. The first part is devoted to the general principles of dietetics, the second part touches on various pathological states in which dietary treatment may be indicated with both the "why" and the "how." The third part gives specific diets applicable to these diseased states together with many recipes. Tables of chemical composition of foods are appended.

There is nothing unique in form or subject matter. The book is recommended as a good elementary text on the subject of nutrition and dietetics.

GEORGE E ANDERSON

A Primer for Diabetic Patients. An Outline of Treatment for Diabetes with Diet, Insulin and Protamine Zinc Insulin. By Russell M Wilder, M D. Sixth edition, reset. Duodecimo of 191 pages, illustrated. Philadelphia, W B Saunders Company, 1937. Cloth, \$1 75.

Every effort made to popularize the knowledge of the diabetic state will meet with the approval of the conscientious practitioner. Dr Wilder's sixth edition of his *Primer* includes mention of protamine zinc insulin and also the hereditary aspects of diabetes. Special mention is deserved by the quiz section at the end of each chapter, a feature which makes more compulsory the reviewing of the material read previously. The special section by Paul L. Tarara, Chiropractor to the Mayo clinic, on the importance of the care of the feet is also a feature frequently overlooked.

DAVID GLUSKER

Approved Laboratory Technique. Clinical Pathological, Bacteriological, Mycological, Parasitological, Serological, Biochemical and Histological. By John A. Kolmer, M.D., and Fred Boerner, V.M.D. Second edition. Quarto of 803 pages, illustrated. New York, D. Appleton Century Company 1938. Cloth \$3.00.

The first edition of this book enjoyed wide popularity, especially among pathologists and laboratory technicians. The second edition deserves even greater usefulness because of its completeness. In this edition, the authors have covered the laboratory field widely and well, and in the compass of a single volume have been able to supply both detail and quantity.

In addition to a revision of the older text, there have been many additions. New chapters have been added on—the methods for the hormone diagnosis of early pregnancy, hydatidiform mole, chorionepithelioma, teratoma of the testis, on diagnostic mycological methods, on methods of examination of the skin and mucous membranes for animal parasites, on methods for conducting tests for allergy, and on histological methods of preparation of museum specimens. A departure from the first edition is the preparation of many of the chapters by a group of collaborators who are recognized authorities in the fields about which they write. Special commendation is due to the authors for the stress laid on the field of mycology and parasitology, a branch of

laboratory medicine that has until now received but scant attention in volumes of this kind.

A chapter worthy of mention is the one dealing with the methods for examining feces. This is singularly complete and is adequately illustrated by many actual photographs of the various parasites found in the stool.

The section dealing with general bacteriologic methods will be found to be very useful, and the various tables dealing with the identification of the common pathogenic anaerobes will no doubt be a great help to the bacteriologist. It is unfortunate that such scant information is provided in the section dealing with the serological types of pneumococci, and there has not been sufficient stress laid on the importance of the so-called Group IV pneumococci as virulent pathogenic types producing typical and often fatal pneumonia. The reviewer feels that it is erroneous to state that strains belonging to Group IV are the least virulent. Similarly, in the Neufeld reaction, little or no stress is laid on the significance of cross reactions.

All in all, the authors are to be commended on the thorough revision of what is already becoming a standard text. This volume deserves a place in the library of every clinical laboratory, and will be found useful by practicing physicians who perform the simpler laboratory tests for themselves.

THEODORE J. CURPHEY

An Introduction to Dermatology. By Richard L. Sutton, M.D. and Richard L. Sutton, Jr., M.D. Third edition. Octavo of 606 pages, illustrated. St. Louis: The C. V. Mosby Company 1937. Cloth, \$5.00.

This is, indeed, an excellent introduction to dermatology, for, despite the fact that it is a fairly small book, it is quite complete. If one wishes to get something of the groundwork of this subject—to quickly and surely obtain the basic facts of anatomy, and physiology of the skin, the general outlines of etiology and

therapy, and to learn the primary and secondary lesions of the skin, together with the distribution of lesions according to type and topography, he will read carefully the first eighty-five pages of text

Following this we find descriptions of the various cutaneous maladies that have been grouped under a more modern classification, wherein the diseases due to viruses, bacteria, plant, and animal parasites, etc., have been removed from their old arrangement and honored with separate groupings. Modern understanding of dermatology is evidenced clearly by the rewritten portions of the book, by the inclusion of a number of diseases previously omitted, and by the revision of the therapy of syphilis to conform with the findings of the Cooperative Clinical Group.

Numerous excellent photographs, many of them new, are scattered throughout the text. For clarity of presentation and comprehensiveness, this book is worthy of inclusion in any library.

E ALMORE GAUVAIN

The Surgery of the Sympathetic Nervous System. By George E. Gask, F.R.C.S., and J. Paterson Ross, M.S. Second edition. Quarto of 191 pages, illustrated. Baltimore, William Wood & Company, 1937. Cloth, \$4.50.

This book is a second edition setting forth some of the further experiences of the authors in the surgery of the sympathetic nervous system. As in the first edition there is a good, briefly stated account of the Anatomy and Physiology of the Sympathetic System, however, no comparable description of the so-called parasympathetic system. In turn there are chapters on Sympathectomy for Disorders of the Circulation, Sympathectomy for Disorders of the Visceral Motor Mechanism and Sympathectomy for pain. Approximately two-thirds of the book is given to a discussion of the surgical treatment of vascular disorders of the extremities. The methods used for sorting out the particular circulatory disturbances that respond favorably to operations on the sympathetic system, have been dealt

with in considerable detail. An opinion has been expressed by the authors that the late results of sympathectomy depend mostly upon the nature of the disease and not upon the powers of the sympathetic nerves to regenerate. This contribution represents the advancements that are being made in this particular branch of surgery and it is recommended as an objective presentation of the present day knowledge on the subject.

JEFFERSON BROWDER

Physicians' Vitamin Reference Book. Presenting to the Clinician a Useful Compendium of the Latest Facts About Vitamins. By the Medical Division, Professional Service Department, E. R. Squibb & Sons. Duodecimo of 126 pages, illustrated. New York, E. R. Squibb & Sons, 1938.

This is a well arranged small book of the present day clinical thoughts on the vitamins. At the beginning of each section for the vitamin considered is a full page summary with the headings synonyms, chief deficiency symptoms and signs, diagnostic methods, Average Daily Requirement, Sources (Foods and Pharmaceutical Products), Uses, Chemical Formula, Stability, Precursor, and Unit of Potency. These and the well balanced list of reference headings given at the bottom of each page of text add to the value of this work.

It can be recommended as an up to date reference on the vitamins for the medical practitioner.

PAUL C. ESCHWEILER

Personality and Other Things (a Semi-Autobiography). By Harold Hays, M.D., Octavo of 163 pages. New York, The American Physician, Inc., 1937.

Dr. Hays is a well known otolaryngologist who has many interests outside of his own particular field, among these are psychology and writing.

The present book is his own views on personality and how to lead a happy and contented medical life. The book is essentially autobiographic in character, but is written with a view of pointing out little things in life that spell success or

failure to the average physician. It is written from a human angle, and relates experiences of the author as well as those of other physicians, many of whom have achieved fame and reputation. There is much in the book that may be read with profit not only by the doctor but also by the layman. There is an appended story written by the author in 1917 while he was in the front lines with a field ambulance of the British Army, which adds to the interest of the book especially in view of the modern undeclared wars.

The book is recommended as a valuable manuscript—both entertaining and instructive.

IRVING J. SANDS

Disease and the Man. By Roger F. Lapham, M.D. Octavo of 143 pages. New York: Oxford University Press, 1937. Cloth \$2.00.

This is an interesting contribution to the ethics and etiquette of medicine. It should appeal particularly to the younger groups of medical men in their earlier years of a career, which, perhaps more than any other, is in touch with a comprehension of the frailty of human nature and a science which is ever struggling toward exactness. The author has vision, clarity of expression, and high ideals, which give evidence of a cultural background. In 145 pages he presents clear pictures of the relationship between patient and doctor from many angles, and suggests practical methods in the handling tactfully of difficult situations. The book is full of good, sound common sense and should be a welcome addition to the libraries of physicians who, for lack of experience which time only can bring, find themselves in need of reliable advice.

J. M. VAN COTT

Obstetrics for Nurses. By Joseph B. DeLee, M.D., and Mabel C. Carmon, R.N. Eleventh edition. Duodecimo of 659 pages illustrated. Philadelphia, W. B. Saunders Company, 1937. Cloth, \$3.00.

This standard and practically universally accepted American text on obstetrics for nurses has recently appeared in its eleventh edition. As Dr. DeLee states

in the preface, "it is now thirty-three years since the first edition of this work." The eleventh edition has been notably enlarged by the collaboration of Miss Carmon, Instructress in the birth rooms of the Chicago Lying-in Hospital. It is of interest to note that Dr. DeLee states that he obtained this collaboration "because of the growing hospitalization of maternity cases and the need of a fuller consideration of institutional technic."

The fundamentals of nursing obstetrics are presented in the clear and concise manner so characteristic of Dr. DeLee as a teacher and author. The portion of the text devoted to nursing during labor and in the puerperium warrants special comment because of the complete manner in which surgical aseptic technic from the nursing standpoint is presented.

This edition brings up to date the already established reputation of the text as a foundation work for nurses. It must occupy a prominent place in the list of required reading in all training schools for nurses. It may well be read carefully by every hospital obstetrician.

ONSLOW A. GORDON, JR.

A Method of Anatomy. Descriptive and Deductive. By J. C. Boileau Grant, M.B. F.R.C.S. Quarto of 850 pages, illustrated. Baltimore: William Wood & Company, 1937. Cloth \$6.00.

In view of the fact that so much has been said in praise of this book, it is possible that an initial and cursory examination may for some be a little disappointing. However, further examination of the text, and a little study of the illustrations will soon change any disappointment to an enthusiastic appreciation of what the book contains.

The descriptions are unique and wonderfully concise. They cover matter that is not readily found elsewhere. The manner of emphasizing the logical arrangement and the positions of various structures, in describing relations, makes the study of anatomy less of a memorizing task and more of a reasoning process.

The illustrations serve their purpose almost perfectly. They are noteworthy

in that all material extraneous to the parts under consideration is omitted and hence does not tend to confuse the picture. They are extremely helpful in visualizing relations that are not nearly so well expressed by much more elaborate illustrations contained in the commonly used textbooks in anatomy.

For reviewing the anatomy of some particular part of the body, whether for teaching or for clinical application, reference to this book will be well repaid.

WALTER H. SCHMITT

Muir's Bacteriological Atlas Atlas Enlarged and Text Rewritten by C. E. van Rooyen, M.D. Octavo of 90 pages, illustrated. Baltimore, William Wood & Company, 1937. Cloth, \$5.25.

This is an expanded edition of the teaching atlas originally derived from the didactic plates of the late Dr. Richard Muir. His drawings have been mostly retained, but ten years of advancement since their first publication has made necessary additional material and illustrations in addition to a thorough revision of text. Criticisms of artificiality and exaggerations of detail are minimized by the splendid reproductions. Illustrations of bacteriologic findings in various virus infections are of particular interest. The purpose of portraying to the beginner what may be seen when properly focused on specific material is well met and not hampered by the simple descriptive text. The student and instructor will be well repaid by the union of this volume with his selected textbook.

IRVING M. DERBY

Pre-Natal and Post-Natal Management. By J. St. George Wilson, M.B., F.R.C.S. Octavo of 206 pages, illustrated. Baltimore, William Wood & Company, 1937. Cloth, \$4.00.

The medical supervision of expectant mothers should be preventative in outlook and educative in scope. The author

of this small volume has admirably shown how both these desirable objects may be attained.

Prenatal care *per se* will never materially lower maternal morbidity and mortality, but it will reduce to a considerable extent, or even perhaps eliminate, the complications of pregnancy, and help to ameliorate the symptoms of those lesions already existing when the pregnancy began. Indeed, it will tell when to terminate the pregnancy where alarming symptoms are impending or actually present.

We may well ask, what is adequate prenatal care without good intrapartum management? Very little. The admonitions given by Dr. Wilson for the management of the intrapartum period are sound and practical, and if heeded by every practitioner would greatly reduce the existing rather high maternal morbidity and mortality rates.

Your reviewer must take issue with the author (Chapter XI) in regards to the induction of abortion and labor. The use of Lamanaria tents, "stomach tubes" or bougies, withdrawal of the liquor amni, etc., are of questionable value. This is true because we believe that the likelihood of infection from such methods, not to mention the pain and discomfort to the patient, far outweighs the ease, on the part of the physician, with which these procedures are carried out. Other methods, particularly surgical, are far more satisfactory. If the practitioner is not capable of performing these surgical procedures he should put his patient in contact with some one, not necessarily a specialist, who is capable.

All in all, this volume is informative, authentic, well written, and up to date, and can without hesitation, be recommended to the profession.

HARVEY B. MATTHEWS

ORDERING BOOKS

As a service to our readers, books listed in this issue or any other medical book in print may be ordered through T. H. McKenna, Inc., 878 Lexington Avenue, New York City. Phone Butterfield 8-6603.

NEW YORK STATE JOURNAL *of* MEDICINE

VOLUME 39

FEBRUARY 1 1939

NUMBER 8

Editorial

A Deliberate Foul

It is interesting to observe the unanimity of editorial opinion throughout the country on the indictment of the A M A for "restraint of trade". Even papers favorable to socialized medicine admit that the government's action is a subterfuge to create propaganda for the National Health Program soon to be submitted to Congress and to force the profession into submission. With few exceptions the press condemns this flagrant misuse of the Anti-Trust Laws.

The impending trial raises many interesting points, not least among them whether the practice of medicine is to be removed from the ranks of the learned professions and classed henceforth as a trade. If the latter, it will furnish an argument for trade union methods by the profession to obtain better working conditions and a greater measure of economic security.

A closed shop is one of the first demands of organized labor. Under the Roosevelt Administration the government has thrown its influence behind this principle. Presumably if the doctors had a union the closed shop would be all right for them too. At present, however, it is "restraint of trade" when the profession prescribes ethical and scientific standards for medical practice.

Maybe the profession would be better off if it were officially designated as a trade and received the right to bargain collectively and perhaps engage in a sit-down strike or two to obtain shorter hours and better pay. It is true the public might suffer if physicians insisted on a forty-hour week, with time-and-a-half for overtime, but the Administration would be bound to sympathize with the latter's aims and methods once they were officially classed as

“labor ” What is unlawful “restraint of trade” in a professional association is approved policy for trade unions

Under the circumstances, the government may find itself with a Pyrrhic victory on its hands if it wins its case against the A M A. Fortunately, victory is far from assured

When we say “fortunately,” we are thinking of the public no less than the profession. Even if Mr. Arnold obtained only a consent decree covering the situation in Washington, it would give the Department of Justice Gestapo-like powers over medical practice which it is in no way qualified to exercise

The Administration’s underhanded attack upon the organized profession is hardly less of a disservice to the public than to physicians. In the last analysis, the success of any health program depends upon the willing co-operation of the profession and the unshaken confidence of the people in its doctors. How can the Administration expect either when it has gone out of its way to misrepresent the views and impugn the good faith of the profession?

Win or lose, the government will find that it has paid a high price for the fun of throwing mud at the country’s physicians because of their refusal to assume the role of yes-men in violation of their professional convictions

Familiar Complaints

The results of the Regents’ Inquiry Into the Character and Cost of Public Education throw cold water upon the hopes of those who believe that state control of medicine would improve the public health. According to a recently published report, the health program in many of the school systems in New York State is decidedly inferior, with waste and incompetence actually endangering the welfare of millions of pupils

Dr. C. E. A. Winslow, Professor of Public Health at Yale, and a noted advocate of state medicine, conducted the Regents’ Inquiry into the School Health Program. He surely cannot be accused of prejudice against public medicine. Yet he reports substantially the same failures as organized medicine attributes to state-controlled practice

Physical examinations in many schools (as in many panel practices) are practically worthless because of the pressure of time. In some schools the unfortunate doctor is obliged to examine fifty children in an hour—and this is not a maximum figure. It goes without saying that early or hidden defects cannot be unearthed

Dr. Winslow finds a serious danger to the mental health of school children in the retention of teachers who are unsuited for their work

Neurotic, maladjusted teachers produce neurotic, maladjusted pupils, but it is almost impossible to oust teachers for this reason

It cannot be said that the authorities have had no knowledge of these evils. Organized medicine has repeatedly called attention to the futility of hasty mass examinations of school children by physicians with no knowledge of the past or familial medical history of their patients. The Chief Medical Examiner of the Board of Education in New York City has crusaded for years against the retention of neurotic teachers in classroom positions.

The fact is that the public purse is not unlimited, any more than the private purse is. In a family the parents' only concern is to get the best possible medical service out of available funds. Under governmental systems, the administrative bureaucracy must be provided for first, and what remains for actual medical care is often very meager. Add political interference to bureaucratic costs, and you have a fair explanation of why most state systems of individual health service fail to come up to popular expectations.

As the Winslow report states: "In many localities the school health service is operated in spite of open opposition on the part of the doctors. If this opposition has been considered at all it has been only to have it dismissed as being due to jealousy, lack of vision, and lack of co-operation on the part of the doctors engaged in private practice. Little thought has been given to the contention that the medical profession, in its routine practice, could, if unhampered by unfair tactics, definitely improve the health not only of the school children but of the whole community."

On the Witness Stand

Let the doctor say whether he wants to be healer or "heeler." Let the patient answer whether he wants to be considered a sick and suffering individual or "a statistical item." Shall our citizen remain the potent factor in our electorate, or will he become instead a cog in the mechanism of a medico-political bureaucracy which will control him, and the state too, eventually? Shall thrift, initiative, and self-reliance give way to tax burdens which neutralize thrift, prevent savings, and destroy initiative, and our profession, by and large, become a job hunting and job holding fraternity? Shall the stress in the education of our youth entering into the study of medicine be changed from the search for the secrets of Nature to alleviate suffering, to that of training to become a properly subservient official to the bosses in the scheme, and the sick, a suspect always under the scrutiny of medical officers on the watch for malingering, or fearing that in some medical official the

healer had not quite been killed, and the patient was therefore getting better service than the scheme allowed!

Working from source material comprising many books, hundreds of pamphlets and the reports of foundations and committees, in addition to making summations from questionnaires sent to governors, state health departments, local health officers, college professors, hospital executives, and private physicians, J Weston Walch presents the interested public with a new edition of his little pamphlet, *On the Witness Stand*

It is interesting to note, in passing, that the stand on the question of compulsory health insurance which Mr Walch takes was no pre-conceived one. Engaged as he was in furnishing to young debaters and their teacher-coaches material from which they could assemble their arguments both pro and con, and realizing that they want to consider the facts dispassionately and are not swayed by emotion, he soon found, in spite of his evident desire to be neutral, that the very assembling of the facts inevitably pointed to two outstanding features, namely that the people of America were healthier than the people of countries with compulsory health insurance, and that there was very distinct evidence plainly indicating that the system of compulsory health insurance does not render efficient and satisfactory medical service.

We agree with Mr Walch that the American people are facing a very important decision, and that compulsory health insurance with its inferior medical service and its inevitable burden of bureaucracy would do irreparable damage to America, and we know that he is right when he says, " I also feel that if the American people learn the facts, unprejudiced, there will be no question as to their reactions "

In the interest of supplying the public with the facts in a short, easily read little pamphlet, our Society has the newly revised edition of *On the Witness Stand* available. Every one of us should read it carefully, and pass it on to our nonmedical friends, for if Eliot's five-foot shelf carried the essence of a college education, this little pamphlet carries not only the mastery of this topic of the hour, but it poses certain questions which must be answered. This little pamphlet gives some of the answers.

Forensic Neuropsychiatry

In no branch of forensic medicine is expert testimony open to so much question as in the field of neuropsychiatry. Not only in the evaluation of responsibility for antisocial acts, but in the deter-

mination of casual relationship between trauma and nervous disorders as it affects the just decisions of claims at law, forensic neuropsychiatry is at a distinct disadvantage. So evident is this fact that, as Keschner points out in his article on page 218 of this issue, many physicians with high professional standards voluntarily exclude themselves from the field of compensation practice.

Keschner points out that the profession is to a degree at fault, but that the larger fault lies in what law expects from the expert. This Keschner discusses thoroughly and indicates clearly the remedies for the correction of these errors. Were these carried out fully, forensic neuropsychiatry would then be established as having a definite function in the administration of the law, instead of the haphazard one it now has. This article merits careful study by both the legal and the medical professions.

Medicolegal Problems of Carbon Monoxide

Poisoning by carbon monoxide has assumed added significance from a medicolegal aspect as clinical observation and experimental studies have contributed to a broader understanding of the action of this gas on the human mechanism. According to Beck,* there are three phases which carbon monoxide poisoning can assume. Acute asphyxiation is the result of an attempt at suicide or it is accidental, and so presents no difficult medicolegal problem. Where, however, following acute asphyxiation, recovery ensues, there may develop within a week after the incident severe cardiac or cerebral symptoms due to the anoxemia. The signs of myocardial insufficiency or coronary occlusion may become manifest or the picture may be that of an encephalitis. In this group there often arise claims for disability, and unless a careful history is taken and a knowledge possessed of the pathology of anoxemia, carbon monoxide may not be considered as the etiologic factor and thus a just claim be denied at law.

It is in the third group, comprising the chronic poisoning, that the greatest medicolegal controversy exists. It is not yet generally accepted by the medical profession that disability, and even death, may be the result of slow, persistent poisoning from the inhalation of carbon monoxide. Such sequelae are apt to occur in persons who work or live in places where there are open gas heaters but no flue for ventilation. They may also happen from the exposure to sublethal quantities of the gas while driving in a closed automobile which

* Beck, H. G.: *Am J Med. Jurisprud.*, 1 145 (Nov) 1925

has a defective engine or exhaust. While the most common symptoms here are those usually associated with the mere want of oxygen, it is possible for one so exposed to suffer the same ill effects as those noted subsequent to recovery from acute asphyxiation.

Beck feels that the recognition of these factors is essential in order that the benefits from workmen's compensation and other disability insurance may be broadened to include these little recognized complications which may be either late manifestations of acute poisoning or the result of prolonged exposure to small quantities of carbon monoxide. From the medicolegal standpoint, experts at law cannot be expected to establish new standards for compensable disease until such standards have been generally accepted as facts by the experts in medicine upon whom they depend for the solution of such problems.

The Distribution of Physicians in the State of New York

Elsewhere in this issue is a fine, carefully made study of the distribution of physicians in our state. Dr. Joseph Lawrence, our energetic executive officer, has compiled the results of his continuing studies of this problem since his last report made in 1929. This type of survey has had publication each decennium since 1878.

It would detract somewhat from the interest our readers would have in the perusal of Lawrence's masterly work, did we attempt to summarize it. It deals with nurses, hospitals, and maternity homes, as well as laboratory facilities, communications, and sanitary conditions as well as with the distribution of doctors and the ratios they hold to both urban and rural populations.

The density of the population somehow seems to regulate the numbers of resident physicians, and it is interesting to note the lag which is evident in the trek of physicians away from localities where population decreases. The doctor is prone to delay uprooting himself and moving on, as the density of population decreases. Eventually, however, he follows the population's trend.

One outstanding factual observation and conclusion is especially noteworthy, and social workers and legislators would do well to study this survey and mark this fact. *There is no area in this state without medical care.*

We heartily commend this survey and recommend its perusal by all. It comes advantageously timed, when there are those who would saddle our state with a heavy burden to support a medicopolitical bureaucracy to handle a compulsory health insurance scheme, somewhat predicated on the absence of available medical care in our state.

Current Comment

" The more we cultivate truth our selves, mix with truthful men, test the accuracy of our words before we speak them and of our writings before we let them go abroad, develop in our consciousness by the study of writings that time has shown to be redolent of truth, not alone those of surgical masters but of all great men, an orientation that will lead us to truth as the pigeon is led to his own cote, the more certain will be our instinct, the more direct our intuition. Blessed are the truthful, for they shall see truth. We have quoted from "Truth," a dissertation by W. H. Ogilvie of Guy's Hospital, London, which can be read in its excellent entirety in the November, 1938, issue of *Surgery, Gynecology and Obstetrics*.

' It is our business ' said the Attorney General, 'to see that restraints of trade and coercive practices are stopped.' Certainly a sentiment laudable in motive, don't you agree? Whether applied to a professional association or a labor union?

"At the moment, Sir, we do roast upon the spit before the hot fire of political righteousness. But when our alleged 'coercive practices' shall have been thus purified, what then? Who next shall be skewered? You, Sir, are as good a prophet as I, who am no Daniel! And so a friendly word of warning, with the compliments of the holiday season. Watch your step! It is barely possible that the Attorney General means what he says.' From a letter written by Laurence D. Redway, M.D., editor of the *Westchester Medical Bulletin*, to Mr. John L. Lewis, and to be found in full in the January, 1939, issue of that bulletin.

" If, perhaps, the monetary rewards for services have not been as great as in more prosperous years, physicians have at least the satisfaction of knowing that

much of their work has made the lot of many beings more livable, and that thought, alone should bring gladness to the heart.

The healing art guild is truly a noble one, and its faithful disciples are fortunate in being able to render that peculiar aid which makes the world, for a host of persons, a far brighter and more attractive place.

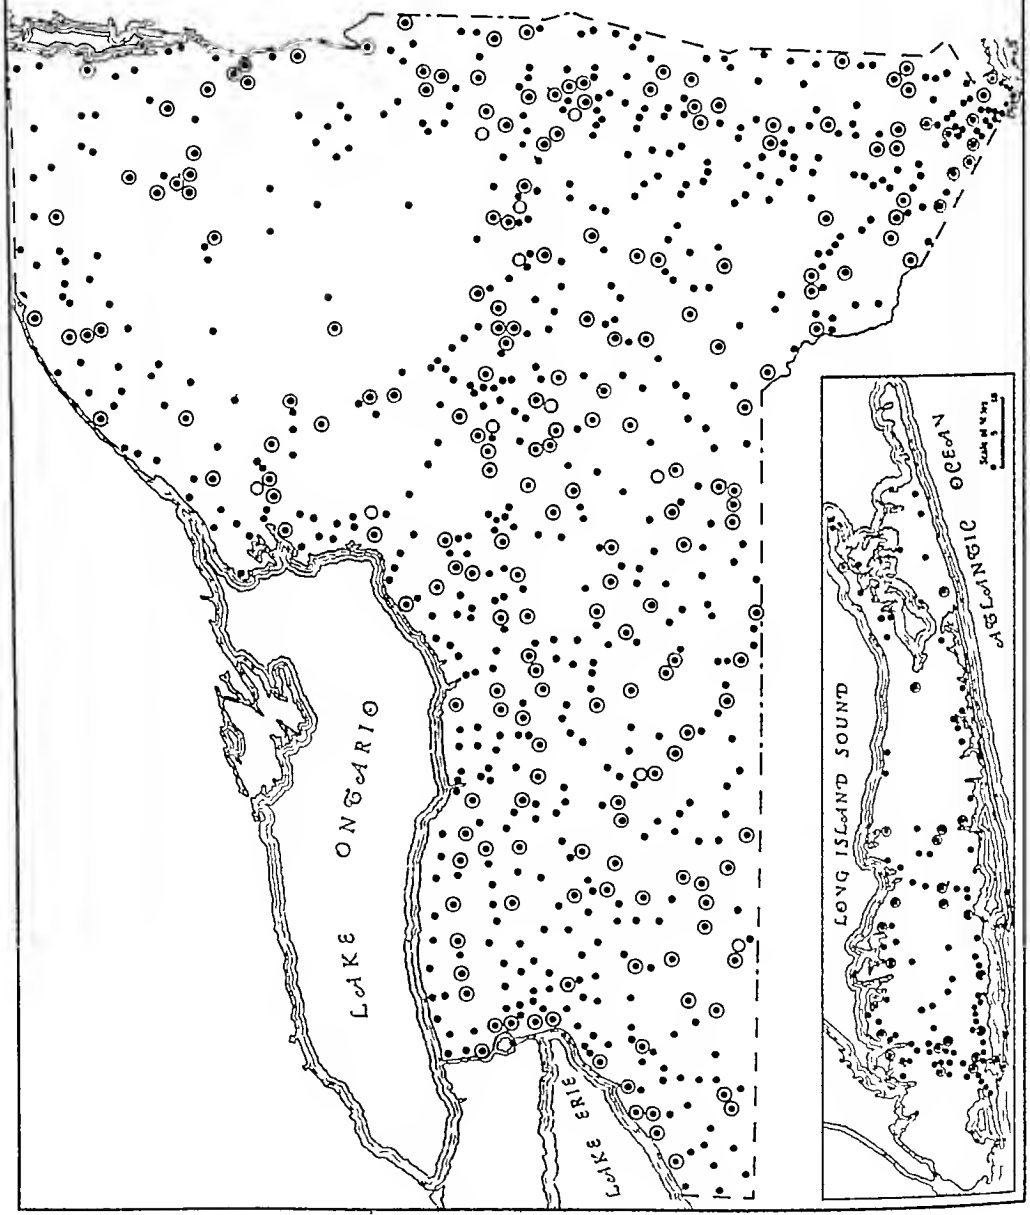

May the physicians of California therefore, in the year to come be recipients of the kindest thoughts and expressions from grateful patients and may they also ever be animated by an earnest desire to move forward, shoulder to shoulder, in meeting the problems which confront both scientific medicine and modern day civilization. New Year's greetings from the editors of *California and Western Medicine* to the practitioners of California in the December issue of that journal.

Everybody is in favor of better health conditions, but it is important to keep in mind as discussion of a new national health program continues, that political or bureaucratic control is not essential to those better conditions. *The Kansas City Star* recently

We admire and respect honest unionism for its fight to raise the standards of American workingmen. Since no one can say what the future holds for medicine, it is possible that the time may come when physicians themselves will have to call upon labor to aid them in a battle to raise their own standards of living. We already have the horrible example in some of the European state-controlled systems where neither the patient nor the doctor receives what is justly due him. From a current issue of the *Milwaukee Medical Times*.

- Communities having one or more physicians
- Communities having hospital or maternity home

(The five counties of New York City—Bronx, New York, Kings, Queens and Richmond—are not included)

A STUDY OF THE DISTRIBUTION OF PHYSICIANS IN NEW YORK STATE

JOSEPH S. LAWRENCE, M D., Albany, N. Y.

THIS report is made as the continuation of a study* reported ten years ago by the author on the distribution of physicians in New York State compared at ten year intervals from 1878. The former study was inspired by a multiplicity of comments from the press, public speakers on public health, and representatives of certain philanthropic agencies to the effect that the rural districts were inadequately supplied with medical service and that which was available was of markedly inferior quality. The data for that study were collected from the Medical Directory of New York, the Medical Directory of the American Medical Association, and records from the State Departments of Health, Education, and Highways, and the Federal Census Bureau. The same sources, supplemented by material from the State Department of Social Welfare, were used in this study. The former study showed that the ratio of physicians to population in New York State was higher than in other states and much higher than in European countries, that the average rural resident physician was but slightly older than the urban resident physician, and that where the physicians were leaving rural practice for urban residence they were simply following the trend of the population of those countries. It was observed that the decreases in the population were noticeable a decade or more before there was an appreciable reduction in the number of physicians. The reduction was so gradual that it was apparent it was not occasioned by any great number of physicians suddenly changing their fields of practice, but more likely due to the death of the older men and the disinclination of young men to locate where the popula-

tion was fading. This study confirms those findings and shows that the same factors are still operating.

Scientific advancement in medicine is promoting specialization and specialists must depend upon concentrated population for sufficient practice, and such specialized hospital and laboratory facilities which they require can be had only in the larger cities. This is a newer factor that helps give a higher concentration of physicians in the urban districts, but it is the general practitioner who is first called by the sick, and while there are no data available to prove the point, it is conceivable that the ratio of population to general practitioners may not be any lower in the cities than in the rural areas.

In the entire state the population has increased 167 per cent in the last sixty years, while the number of physicians has increased 477 per cent. In upstate areas the increases have been 86 per cent and 256 per cent, respectively. The ratio of physician to population in the entire state is 1:576 while in upstate alone it is 1:720. In Greater New York the ratio is 1:497 and in Manhattan and Brooklyn, where there is the greater concentration of specialists, the ratio is 1:387. The increase in the population of these two boroughs in the last sixty years is 146 per cent, while the physicians increased 581 per cent. While the physicians increased much more rapidly than the population, the increase in some rural counties was much greater, for example, Orange County, where the population increased but 50 per cent, the physicians increased more than five times that much, 288 per cent, Rockland, population increased 124 per cent and physicians 093 per cent, Warren, population increased 40 per cent and physicians 319 per cent.

* New York State Journal of Medicine, August 15, 1929.

Among the factors, aside from the population, which have a bearing on the quantity and quality of medical service in the rural districts of the state, are living conditions for the doctor and his family, and means of transportation and communication

One of the greatest deterrents to a young physician locating in a rural area a few years back was the inability to provide satisfactory educational facilities for his children, but the rapid extension of the Central High School in rural districts and free transportation for the children have removed that difficulty. He can readily equalize the other living conditions

Communications

In 1878, the principal highways were turnpikes on which tolls were collected and efforts were made to keep them open in winter, but by far the largest proportion of the roads over which the doctor had to travel day and night, summer and winter, were soft dirt roads that were almost impassable in winter and spring. Today 62 per cent have a hard-top finish and are kept usable in all seasons. Even the byways into the farms are far superior to what they were sixty years ago. It can safely be said that because of the improved highways 95 per cent of the population of rural New York live within fifteen minutes' travel of a resident physician.

In these sixty years, in addition to the automobiles and good roads, the telephone has materially reduced the distance between the patient and the doctor. A large percentage of the population have telephones, and although every family does not possess a telephone, a neighbor is sure to have one.

Sanitary Conditions

In these sixty years miraculous hygienic changes have occurred in the living conditions of the state and some of the benefits have extended to the most remote farm or camp. Water and milk supplies are kept pure and epidemiologists from the Department of Health ferret out the

source of every communicable disease immediately that it is discovered and establish suitable conditions of quarantine. In 1878 there were annually in every district of the state quantities of cases of typhoid fever, diphtheria, dysentery, smallpox, and tuberculosis, while in 1937—the latest figures available—the reports showed that in the entire state for that year there were only 576 cases of typhoid fever, 1,387 of diphtheria, 1,066 of dysentery, 72 of smallpox, and 16,051 of all forms of tuberculosis. These are all troublesome diseases requiring much time from the attending physician. The extent of their presence or absence must surely affect the demand for the physician's services.

Irregular Practitioners

Of course, these records relate only to the licensed physicians, since there is no way of accurately ascertaining the number of irregular or unlicensed practitioners. Probably they were more numerous then than today, but it does not seem likely, for they find conditions improve for their practice as the population grows in density.

Age of Physicians

Commentators today are less frequently heard to speak disparagingly of the age and scientific qualifications of the rural physician, but some of them still advocate that the state should be responsible for bringing more physicians into the rural districts. In this state the means of communication are so superior that the city physician does not hesitate to cultivate a more or less rural practice and the rural resident physician frequently extends his practice into the city. Laboratory and hospital facilities are readily available to the rural resident physician, and journals and county medical society postgraduate courses help him keep abreast of the times as well as the urban resident physician.

The conditions and opportunities of the rural and urban physicians being so nearly equal, one might expect the periods of practice to bear a close resemblance,

and they do. Approximately 25 per cent of the physicians in both areas have been in practice less than ten years and another 20 per cent to 25 per cent have been in practice less than twenty years. The assumption that the recent graduate shuns rural practice is only partly correct. Many seek rural locations but, not being successful, are eventually obliged to locate in the cities. But there is another factor operating. Not a few physicians, seeing their most prosperous families forsake the farms for the cities, have followed them advantageously.

Distribution of Hospitals and Maternity Homes

Modern practice requires readily available hospital and laboratory service. There is only one county in the state, namely, Hamilton, which does not have a hospital, but it is largely included in the Adirondack Park and has a resident population of less than five thousand people. It is estimated that 85 per cent to 90 per cent of the population of the state are within an hour's drive of a well-equipped hospital. The hospitals are supplemented by many maternity homes. There are distributed throughout the state, at strategic places, maternity homes where physicians can take a woman whose home facilities are not satisfactory or who does not want to go to a hospital to be delivered. Many of these homes are provided by graduate nurses who equip their homes with a bed or two and proper sterilizing facilities and serve as the nurse.

Besides the laboratory facilities provided by the hospitals, the Division of Laboratories of the State Department of Health has approved more than thirty-five laboratories where examinations for communicable diseases are made and pathologic tissue studied. The facilities of these laboratories are available to all doctors and examinations are free. Through the laboratories the Department of Health also distributes free of charge to the physicians certain therapeutic agents such as vaccines, antitoxins for diphtheria and tetanus serums for pneu-

monia, and drugs used in the treatment of syphilis and prevention of ophthalmia neonatorum.

Nurses

There are between 1,700 and 1,800 nurses in upstate engaged in some form of public health work. Approximately one third of these are employed by boards of education to care for the pupils and to assist in giving courses in health education. Only about one fifth are employed by boards of health. The full benefits of adequate public nursing services and the part nurses can take in the development of a public health program are not thoroughly understood as yet. The State Department of Health is giving especial attention to this problem. The work now is spotty, some counties are doing splendid work while others, for reasons of their own, principally financial, are showing very little interest.

In this study the number of nurses employed by the state and municipalities are particularly indicated. The others are employed by such agencies as the Red Cross, industries, insurance companies, and voluntary groups interested in some form of health work, as committees on tuberculosis, maternity, and cancer.

Deductions

1 Resident physicians and hospitals are distributed throughout the state in such fashion that no area is without medical service. Schuyler County has the lowest ratio of physician to population, 1 1,298, and the highest is in Dutchess County, 1 478. In the relation of general hospital beds to the population, the lowest is found in Livingston County, 1 1,644, and the highest ratio exists in Ontario County, 1 84. In evaluating these figures, it must be borne in mind that no county is an isolated unit, so that the services of physicians and hospitals of neighboring counties are always available.

2 Improved conditions for transportation and communications in the rural districts have increased the useful

ness of the physician many times over what it was just ten years ago

3 The same conditions have led the rural resident to seek the services of the city physician except for emergencies In some instances this trend has induced rural physicians to move to the cities, at the same time retaining their rural practices

4 None the less improved living conditions are attracting young men to locate in the rural areas

5 There is no marked difference in the ages of the men practicing in the rural districts as compared with those in the urban districts

6 Decreases in population must be marked and prolonged before there is any effect upon the number of physicians Areas of growing population have larger proportions of young physicians

7 Nursing service as a part of a public-health program demands prompt study

Ratio of Population to Physician*

ENTIRE STATE: 316 general hospitals with 82,245 beds ratio—1 bed to 259 population

NEW YORK CITY: 125 general hospitals with 32 722 beds ratio—1 bed to 229 population.

UPSTATE: 191 general hospitals with 10 523 beds ratio—1 bed to 311 population.

These ratios are prepared on the hospitals listed in *The Journal of the American Medical Association* for March 26 1938. There are a number of hospitals doing general work acceptable to the communities that are not in this list.

FORENSIC NEUROPSYCHIATRY

MOSES KESCHNER, M D , New York City

IN VIEW of the frequency with which neuropsychiatric problems are important issues in criminal, testamentary, negligence, and workmen's compensation cases, it is difficult to explain the lack of interest in this subject on the part of most neuropsychiatrists in this country. The possible reasons for this attitude may be (1) the erroneous belief held by some that the practice of forensic neuropsychiatry demands contacts with lawyers and politicians—contacts generally regarded unpleasant and distasteful to scientifically minded individuals, (2) the general lack of interest in forensic medicine—especially in forensic neuropsychiatry—by medical educators in this country.

Most medical schools fail to provide well organized instruction in these subjects. In a recently established course in forensic medicine in one of the metropolitan medical schools the only reference in the curriculum to forensic neuropsychiatry reads as follows: "Some facts relating to the medicolegal aspects of mental disease are discussed and instruction is given in the examination and commitment of the mentally sick." Since the World War the general public has become more or less mental-hygiene conscious with the result that several of our educational institutions became interested in criminology, and some excellent courses are now offered in this subject, most of these, however, are devoted more to the sociologic than to the biologic aspects of the problem.

Forensic psychiatry in its relation to criminology pivots around the question of mental responsibility of an individual charged with the commission of an anti-social act. Psychiatrists encounter great difficulty in attempting to reconcile the psychiatric with the legal point of view as to mental responsibility. It is high time that the meaningless terms of legal insanity and medical insanity be discarded. That this view is also held by some en-

lightened judges is well exemplified by the following statement by Judge Doe in a recent case: "That cannot be a fact in law which is not a fact in science, that cannot be health in law which is disease in fact. And it is unfortunate that courts should maintain a contest with science and the laws of nature upon a question of fact which is within the province of science and outside the domain of law." The determination of mental responsibility should not be a matter of law. Mental responsibility is a matter of fact to be determined by those trained in obtaining and interpreting the facts regarding human behavior.

The legal standard of knowledge of right and wrong as a yardstick for measuring mental responsibility does not conform to the facts as psychiatrists see them. The law is interested in the criminal act, whereas psychiatry is chiefly concerned with the individual who commits it and with the determination of the presence or absence of organic brain disease or of a personality defect that may account for the commission of the crime and the unconscious motivation of the act.

The law still adheres tenaciously to concepts of mental responsibility, guilt, and punishment formulated centuries ago. Most of these formulations are based on old concepts of lack of cognition, irresistible impulse, delusion, and monomania. Sheldon Glueck justly criticizes these concepts as tests of mental responsibility in "that their employment as such neglects the fundamental notion of the unity of mind and interrelationship of mental processes and the fact that a disturbance in the cognitive, volitional, or emotional sphere, as the case may be, can hardly occur without its affecting the personality as a whole and the conduct flowing from that personality."

It is to the credit of psychiatrists that they are taking the initiative in the read-

justment of society's attitude toward the crime problem but, as with all reorientations in subjects which concern both the individual and society, there are many obstacles to overcome. One of these is that society has not as yet learned how to relate crime to biology and to social and psychologic factors. Another obstacle is the law's cautiousness in accepting modern psychiatric formulations owing to the uncertainty of the psychiatrist's knowledge in this field. It is this uncertainty of knowledge, which must be admitted to exist, that causes many misinformed persons to criticize adversely the integrity of psychiatric experts who do not agree. These critics forget that honest differences of opinion are encountered daily in various walks of life and that the judges of the United States Supreme Court are not always unanimous in their opinions. Many of the disagreements by medical witnesses are more apparent than real, they are in most cases due to the absurd method of legal procedure during which evidence is attempted to be obtained by insisting that the witness "answer the question yes or no," without giving him an opportunity to explain his views and reasons for the answer.

Another legal absurdity which casts discredit on the medical witness and especially the psychiatrist, exposing him not infrequently to ridicule, is the hypothetical question. In most instances the amount of valuable information obtained from answering a hypothetical question may be said to be in an inverse proportion to its length. The hypothetical question has been properly characterized as a vehicle affording opportunities for lawyers and experts to engage in matching wits and in a metaphysical discussion of nonsensical and obscure questions. The most serious objection to the hypothetical question is that it may include the assumption of only such facts as have been proved or are expected to be proved as favorable only to the case of the proponent of the question. Moreover, the expert himself may not believe in the truth of the facts assumed. Chief Justice Emery of the Supreme Court of

Maine, in commenting on expert evidence as a necessary evil "not much praised or welcomed," speaks of the hypothetical question as follows: "Often the data given are conflicting and even impossible, presenting cases never met with in medical experience. In fine, the hypothetical question rarely presents a case as it is and answers confined to it are, therefore, misleading. So convinced am I of the justice of this complaint that I have never required an answer to a hypothetical question but have left it to the medical witness to answer or not as he pleased."

It has been suggested that the hypothetical question should be abolished altogether, or if it must remain, that it contain only such facts as have been elicited in the evidence and that the expert be permitted reasonable latitude in rejecting inconsistencies and in evaluating evidence which is confirmed by other evidence and, furthermore, that the question be prepared in chambers or in court by the judge and opposing counsel to the exclusion of the jury and all witnesses in the case.

Forensic psychiatry is not infrequently discredited on account of the carelessness with which some psychiatrists approach the problem and on account of the ignorance and dishonesty of others. The latter has recently been caustically commented upon by John Clarke Knox as follows: "But the practice of medicine like the practice of law and other professions is sometimes accursed by men of base natures and of the character of charlatans. These sometimes subject the art to the suspicion that it is but little more than a mercenary trade. The quack and the fraud is to be found both within and without the court room. On the highways and byways of life he preys upon the ignorant and the unwise. Within the halls of justice he perjures himself upon the altar of truth and reflects discredit upon the guild in which he claims membership. At times he raises doubts in the minds of intelligent men as to whether medicine in general, and psychiatry in particular, have any real claim to a scientific basis. Day after day we find

physicians arrayed on opposite sides of a law suit, each will be given the same set of facts, and asked to draw a reasonable conclusion from the evidence before him. Very often the opinions expressed by the opposing physicians are as far apart as the poles, and in all too many instances the opinions are determined not by the facts but by the necessities of the litigant retaining the physicians who gave them utterance. A doctor, it is true, is under great obligation to his patient, and a lawyer, undoubtedly, owes an understanding duty to his client, but the obligation of one, and the duty of the other is no justification for the prostitution of the law and the rightful expectations of organized society."

Unfortunately this severe arraignment of medical experts is, in no few instances, well deserved. It is not an uncommon experience to see in court that medical—and especially psychiatric—experts forget that they are witnesses who, after obtaining the facts, are expected to deduce from them as a result of special knowledge and experience, certain definite conclusions regardless of the effect that these may have on the legal issues of the case. Whenever an expert ceases to adhere rigidly to this principle he assumes the double rôle of physician and lawyer. In commenting on this attitude of some experts Roscoe Pound has said "It has become their job to work out and expound ingenious theories to make every one understand that for other purposes and for other occasions the man was undoubtedly sane."

These defects in the method of legal procedure are gradually being eliminated by the psychiatrists themselves. One significant step in this direction has been the creation of Boards of Certification in Psychiatry and Neurology whose duty it is to certify as to the satisfactory moral and ethical standing and to the competency of experts. Although these Boards have been functioning only for a relatively short time the justification for their existence is becoming more manifest every day by the unusually high type of expert who is beginning to appear in the courts.

The so-called "battle of experts" is gradually being eliminated by the adoption in many jurisdictions of a new procedure in the method of determining the mental condition of an individual accused of having committed a crime. The general basis for this new method is a statutory provision for the examination of the offender by a board or commission of impartial experts appointed by the court in each case or by a standing committee in a state hospital for mental disease. Such boards or commissions are empowered to investigate thoroughly the details of the crime alleged, the offender's family and developmental history, his physical condition including laboratory findings, environment, intelligence, emotional reactions, and degree of responsibility to be attributed to him. The report and conclusions are then submitted to the court but they are also accessible to the prosecuting officer, the defendant's attorney, and the probation officer. Massachusetts was the first state in the Union to enact such a law, the so-called Brigg's Law. This statute is admitted by most psychiatrists and by many legal authorities to be the most progressive piece of legislation yet enacted to secure impartial and unbiased opinions as to the mental condition of those accused of crime. It is hoped that, when similar methods of determining the mental condition of those accused of crime will have been adopted by the various states, the function of the jury will be limited to the determination as to whether the criminal act was committed, as charged, by the accused and that his responsibility, total or partial, which in the ultimate analysis is a question of psychiatric diagnosis, will be determined by nonpartisan physicians intensively trained in neuropsychiatry.

As ideal and consistent as this method of procedure is with modern psychiatric thought, yet there is a legal obstacle which may sometimes defeat both the intent and purpose of such a method. This obstacle is the constitutional right of the accused to have his defense of insanity tried by a jury of his peers. The average jury is usually unable to dis-

tinguish between competent and incompetent experts, and the common law allows experts to be called on behalf of the interested parties so that it may sometimes be impossible to present to the jury clear, unbiased, and impartial evidence. Still, it may not be too optimistic to hope, even without depriving the accused of his constitutional and common law rights, that lawyers, judges, and the public at large may learn to realize that true justice will be best subserved by the universal adoption of some such method of impartial determination of an offender's mental condition as is at present in operation in Massachusetts and in a few other states.

It must, however, be borne in mind that while this reorientation as to procedure is progressing, psychiatrists must not assume an attitude of self sufficiency as to their knowledge of this branch of psychiatry. There are in this field many problems for the solution of which the law looks to psychiatry. Thus a fruitful field for study would be the various types of so-called psychopathy. From 35 to 40 per cent of the inmates of prisons and reformatories are classified as psychopaths, yet we have very little definite knowledge about delinquent psychopaths. Studies like those of dementia praecox should be undertaken from every possible angle. The data obtained from such investigations could then be correlated and so integrated that they would be helpful in our orientation as to the causes of crime and recidivism with a view of a possible modification of the personality of these individuals.

These and similar problems merit the attention of psychiatry, which should be an auxiliary to the legal machinery concerned with the detection of criminals, probation, parole, and penology in general.

The neuropsychiatrist also plays an important role in the administration of the law of accidental injuries.

Injuries to the nervous system resulting from the increasing use of mechanical devices in industry and everyday life are undoubtedly on the increase. This increase is reflected by a corresponding increase in the number of litigated cases

under the Workmen's Compensation Laws and in suits for personal injuries in negligence cases. In the adjudication of these cases, juries, judges, and referees look to the neuropsychiatrist for a determination of the causal relationship between the accident and the injury as well as for an estimation of the degree of disability and of the amount of compensation or money damages, as the case may be.

In view of the law's demand that these determinations be based on reasonable probabilities and not on possibilities, the neuropsychiatrist is not infrequently confronted with difficult problems.

Cases in which an accident has produced structural changes in the injured parts present, as a rule, the least difficulties. The presence of objective evidence of disease in these cases makes a reasonable estimation of causal relationship and degree of disability a relatively simple matter. The problem, however, becomes much more intricate in cases in which, though there is no doubt that the patient had sustained a severe injury, there are no objective evidences of the presence of a pathologic process as far as can be determined by our present methods of investigation. This is especially the case in patients who have sustained a head injury with or without fracture of the skull, and with or without a history of disturbance of consciousness. In these patients the symptomatology may be entirely subjective and the clinical picture so strikingly uniform that it is regarded as a clinical entity to which the designation of "postconcussion syndrome" has been attached. In spite of the unusually large number of these cases and of the extensive experiences gained during the World War, as well as from experimental investigations in animals, our knowledge concerning this group of cases is still nebulous. The reaction of these patients to trauma, the element of claims for compensation or money damages in negligence cases are all additional factors in obscuring many of the medical issues involved. Without prolonged observation it may at times be impossible to determine with any degree of reasonable probability whether

one is dealing with structural changes, functional disturbances, psychogenic factors, or with deliberate simulation, or with all of these

Much of the existing confusion about these cases is attributable to the fact that the technical designations of traumatic conditions encountered in practice change so rapidly in their current significance in the mouths of judges, referees, lawyers, and physicians that it is at times impossible to know whether we all mean the same thing when we attach a given name to it. Take, for example, the term *cerebral concussion*, in some cases this term is applied to convey the idea that the patient is suffering from the effects of diffuse petechial hemorrhages in the brain, in others from diffuse edema, in others from changes in the hydrodynamics of the cerebrospinal fluid in the cranial cavity, in others from vascular spasm and interference with the intracranial circulation, and in still others from contusions in the so-called silent areas of the brain. Our knowledge of the mechanism of cerebral concussion is inadequate, and it is imperative that neurologists direct their attention to an accurate investigation of brains that have been subjected to trauma, taking into consideration the nature of the violence that has produced the pathologic changes in them.

There is no less confusion about the designation "traumatic neurosis." Some neuropsychiatrists employ this term to designate a type of reaction to terror and anxiety and to an emotional state accompanying a life-threatening situation. Others deny the existence of a traumatic neurosis altogether, because they say that in such cases one is dealing only with hysteria, or with neurasthenia or with a psychoneurosis indistinguishable from these conditions when they are due to other causes than trauma. Still others believe that in these cases the trauma serves as an apparent reason for a distress which may actually be due to a pre-existing, though not recognizable, mental or physical disorder, or to conflicts under which the patient was laboring and was, as Reichardt says, "just about to break."

There seems to be no general agreement as to the use of the designation "traumatic encephalopathy." Some employ this term to designate only cases in which there are clinical evidences that structural changes have occurred in the brain following a trauma to it. Others apply this designation to all cases in which physiologic disturbances of cerebral mechanisms are present although no organic changes are demonstrable, whereas still others prefer to designate these cases as litigation or compensation neuroses and regard the symptoms as reactions to the hope for recompense and desire for revenge.

There is no unanimity of opinion as to the significance of a positive encephalogram in cases following head trauma. Some observers are certain that a positive encephalogram is indicative of structural changes in the brain. Other equally reliable observers hesitate to attach such definite significance to positive intracranial aerograms because they claim that thus far no norms for encephalograms have been established as too few controls have been studied, although all observers agree that a positive encephalogram is of diagnostic significance only when taken in conjunction with the entire clinical picture.

As one's experience with these cases becomes more extensive and he is offered the opportunity to study and observe them for a prolonged period, the conviction is forced upon him that in all probability too many cases are pronounced as being psychogenic when they are in fact functional—they are probably due to disturbances in nerve cell function which are not necessarily registered by detectable histologic changes.

The neuropsychiatrist is not infrequently confronted with a most perplexing problem when he is called upon to express an opinion with a reasonable degree of certainty as to the causal relationship between a given injury and the development or aggravation of tumor of the brain, or of the spinal cord, or of a primary degenerative disease of the nervous system or of an endogenous psychosis.

An opinion is presumed to be based on factual knowledge and not merely on a guess. Who has sufficient factual knowledge of the causation of any of the conditions mentioned above to enable him to give under oath an opinion with a reasonable degree of certainty or even probability, affirming or denying the causal relationship between a trauma and any one of these conditions? Animal experiments have yielded no satisfactory information on this subject. As a matter of fact, except for the convulsive state following blows to the head and possibly some tumors, none of the conditions under discussion have ever been produced experimentally in animals. The literature contains as many expressions by authors affirming the production of some of these conditions by trauma as it does by other equally eminent authorities denying such occurrence. Various hypotheses are offered by the former in substantiation of their opinions. Some would attribute the appearance of some of these conditions to vascular damage, others to changes in the cerebrospinal fluid circulation leading to molecular disintegration, and still others to a tearing of the lymph spaces leading to necrobiotic processes in the nerve parenchyma, etc.

Hypotheses are not facts, and opinions based on hypotheses are not opinions but mere guesses. On what hypothesis or theory can one explain the occurrence or aggravation of a disease like amyotrophic lateral sclerosis with its progressive selective involvement of anterior horn cells and the pyramidal tracts, following an injury to the back so slight that the injured man was able to continue his work uninterruptedly during the next five days when it was noted for the first time that the man's gait was spastic? Yet I heard a neurologist testify under oath that in his opinion the amyotrophic lateral sclerosis was due to the injury. The truth of the matter is that our present knowledge of the facts of causal relationship in such cases is so inadequate that any opinion expressed concerning it is of no scientific value, and wholly within the realm of speculation.

In view of what has been said so far, I believe that until such time as the neuropsychiatrist will possess more and definite knowledge as to the etiology and pathogenesis of these conditions, he should not be required to give an opinion as to causal relationship. All that the neuropsychiatrist can offer to the law is the determination of the existence of the condition in question and the degree of disability therefrom. The causal relationship will then have to be determined by some artificial standard based on some such tests as these: (1) Was the injured person able to carry on his usual occupation in a regular manner immediately prior to the receipt of the injury? (2) Was the injured person free from symptoms of the disease from which he is suffering prior to the injury? (3) What was the temporal relationship between the appearance of the first symptoms of the disease and the time of the injury? (4) Is the injured person incapacitated as a result of the disease, and if so, to what extent?

So that, if the injured person was able to carry on before the accident, and was free from symptoms, and if, during a period, not too short nor too long following the accident there developed the physical or mental condition from which he is suffering, and as a result of which he is incapacitated from carrying on his regular occupation, he is entitled to compensation or damages as the case may be. Some such test as this, though not scientific, would in the present state of knowledge obviate the bugbear of causal relationship. Adjudications based on such a test would be more just and would fill the meaning and the spirit of the law of negligence and of the Workmen's Compensation Act.

It has been remarked by persons administering the compensation laws that they are surprised that physicians with high professional standards have excluded themselves from and been excluded from the field of compensation practice. I believe that if the principles that I have suggested were put into effect many more physicians of known integrity and ability would be attracted to this type of work.

Most of the evils popularly associated with expert medical testimony would be overcome and the latter would be raised to a higher level. This would inevitably lead to a better system of justice, and justice as Plato says "does not simply mean the virtue of rendering to all their due, but stands for that harmonious and proportional development of the inner man, by means of which each faculty of his

soul performs its own functions without interfering with the others. Just or virtuous actions consist in the performance of actions agreeable to the nature of the soul, whereas the contrary comprise such as are discordant to a right nature and productive of mental disturbance and agitation."

451 West End Avenue

CONGRESS ON OBSTETRICS AND GYNECOLOGY

The first American Congress on Obstetrics and Gynecology will be held in Cleveland on September 11-15. The preliminary outline of the program for the medical section is as follows:

Monday, September 11, 1939

The Thyroid and Pregnancy
Heart Disease and Pregnancy
Diabetes and Pregnancy
Tuberculosis and Pregnancy
Nutritional Factors and Pregnancy
The Surgical Abdomen Complicated by Pregnancy

The Treatment of Abortions

Tuesday, September 12, 1939

The New Conception of Ovarian Neoplasms
Carcinoma of the Uterus
Endometriosis
Ectopic Pregnancy
Sterility in the Female

Wednesday, September 13, 1939

Reduction of the Operative Incidence in Obstetrics
Labor Complicated by the Contracted Pelvis
Dystocia Due to Soft Parts
Pathology and Treatment of the Third Stage of Labor

Thursday, September 14, 1939

Present Day Fundamental Knowledge of Hormones and Endocrine Glands
Problems of Adolescence
Problems of Menopause
Diseases of the Mammary Gland

Friday, September 15, 1939

Sulfamidamide in Obstetrics and Gynecology
Pyelitis
Chronic Pelvic Infections

Immediate and Remote Complications Following Labor

ROUND TABLES

Running concurrently each day 11:45 to 1:15

The Toxemias of Pregnancy
Genital Infections
Obstetric and Gynecologic Hemorrhages
The Fetus and the Newborn
Forceps, Occiput-Posterior, and Breech Presentation
Anesthesia, Analgesia, and Amnesia in Labor

JOINT AFTERNOON SESSIONS

Monday, September 11, 1939

Neonatal Care

Tuesday, September 12, 1939

Plans for Prevention and Control of Uterine Cancer

Wednesday, September 13, 1939

Extension Education on Maternal and Neonatal Care

Thursday, September 14, 1939

Economic Aspects of Maternal Care

Friday, September 15, 1939

Correlation of and Attempt to Digest all Proceedings

JOINT EVENING SESSIONS

Monday, September 11, 1939

Legal Aspects of Maternity

Tuesday, September 12, 1939

Humanitarian Aspects

Wednesday, September 13, 1939

Sociologic Aspects

Thursday, September 14, 1939

Ethical Aspects

It is figured that hospital bills amounting to \$1,000,000 for about 12,000 babies and their

mothers in New York State will be paid through the Associated Hospital Service this year.

PNEUMONIA IN THE WESTCHESTER COUNTY (NEW YORK) HEALTH DISTRICT,* 1931-1935

EDWARD A. LANE, M D, White Plains, N Y

(Director Division of Communicable Diseases Westchester County Department of Health)

THE general interest in pneumonia that has been aroused in New York State by the campaign to reduce the mortality from that disease through the more extensive and more adequate use of antipneumococcal serum led the writer to assemble some statistical data concerning the recent prevalence of pneumonia in the Westchester County Health District. It was thought that such a study might serve to outline the problem a little more clearly at least in so far as the Westchester County Health District is concerned and that a base line would thus be obtained against which to measure local results.

The data here presented were obtained from the routine office records. Such material while readily accessible, offers but limited possibilities for study and lends itself more readily to descriptive than to analytic treatment. In the case of pneumonia there is a further limitation due to the fact that all forms of the disease are reportable with no distinction made between primary and secondary infections. Since bronchopneumonia occurs as a secondary infection much more frequently than does lobar pneumonia, it would be of some interest to be able to assign quantitative values to each of the pathologic varieties on this basis.

Morbidity

The seasonal distribution of pneumonia morbidity with the greatly augmented numbers of cases in the winter and the spring is familiar to everyone. Expressed in terms of incidence in the Westchester Health District (Table I), 2,581 cases, representing 80 per cent of the total for the five-year period 1931-1935, were re-

ported during the seven months from November to May. While for five year monthly totals, the largest number of cases occurred in January, for individual years, the largest monthly total fell in January twice, in March twice, and in February once.

Figure 1 is a composite presentation of prevalence for the five-year period from July, 1930, to June, 1935, showing the

mean, maximum, and minimum numbers of cases for each month. This type of graph is useful for comparing current incidence with past experience. It brings out for the data here presented the gradual and prolonged nature of the seasonal increase with a plateau effect from January to March. The graph was constructed on the basis of a July-to-June year to preserve the upward sweep of the curve in an unbroken contour.

When the seasonal incidence of pneumonia is presented separately for the lobar and the bronchial forms (Table II, Figure 2), the former is found to exhibit a somewhat greater variation between seasons of maximum and of minimum prevalence. That is to say, there is a relatively larger number of lobar pneumonia cases in the spring and a relatively smaller number in the summer and early autumn.

This suggests that lobar pneumonia is affected to a greater degree by seasonal changes.

Because of the closer conformity of lobar pneumonia to the status of a primary infectious disease, it might be expected that the incidence of that form would be affected to a greater degree than bronchial pneumonia by density of population. A rough attempt was made to

discover whether the effect of such an influence could be demonstrated in Westchester by computing the percentage distribution of cases of each form among the municipalities arranged in three groups, i.e., city of White Plains, twenty-four villages, and the unincorporated portions of the sixteen towns. The result is shown in Figure 3. Since actual density figures for these groups are not known, comparison between White Plains and the village group cannot be made. There is, however, no question about the

fact that the group of towns has a much smaller density than either of the other two groups. It is therefore interesting to note that the number of cases of lobar pneumonia was actually as well as relatively smaller in the town group whereas the reverse was true in the village group with denser population. The absence of the anticipated disparity in the relative prevalence of the two forms in White Plains may be due to the occurrence in 1934 of a large measles epidemic in that

Figure 4 Pneumonia morbidity county health district, 1931-1935. Percentage distribution of lobar and bronchopneumonia by age groups.

city numbering about 1,300 cases. There was a corresponding increase in bronchopneumonia to the extent of about 40 per cent over the number of cases for the next highest year in the 1931-1935 period.

Of the five year total number of cases of all forms, 61 per cent occurred in villages, 24 per cent in towns (unincorporated portions), and 15 per cent in the city of White Plains.

The age distribution of pneumonia is of little value unless considered for the lobar

and bronchial forms separately. The predilection of the latter for the very young and the very old and the more frequent occurrence of the former in early and middle adult life are well known. In the absence of population figures by age groups, the age distribution of cases is shown (Figure 4) by computing the percentage of each of the two forms in the total number of cases at each age group. Lobar pneumonia is thus found to have constituted approximately three-quarters of the pneumonia cases at ages 15-24, 25-34, and 35-44. While this represents the greatest preponderance of cases of this form, lobar pneumonia exceeded bronchopneumonia at all ages except under 5 years and at 75 years and over. The difference in age group 65-74 was, however, very slight. Of the total number of cases for which this information is available (2,858), it will be noted that 56 per cent were of the lobar form.

It was also found that whereas the cases of bronchopneumonia were evenly divided between the two sexes, 58 per cent of the lobar variety occurred in males.

Mortality

The seasonal distribution of pneumonia deaths (Table III, Figure 5) corresponds in a general way for both the lobar and the bronchial forms with the morbidity distribution. There is the same gradual decline during the winter and spring to a prolonged low level in the summer which is followed by a more abrupt rise in the

Figure 6 Pneumonia mortality, 1931-1935, county health district. For town, village and city groups

fall The peak of mortality for both forms is in January

The distribution of deaths from each form by town, village, and city (White Plains) groups shows (Figure 6), when compared with a similar arrangement of cases (Figure 3), a very marked relative excess of deaths over cases in the town group. While this holds true for both forms it is more pronounced for bronchopneumonia of which the town (rural) group of municipalities had 50 per cent of the deaths but only 29 per cent of the cases. For lobar pneumonia the percentages are 28 and 21, respectively. Two possible explanations for this inequality suggest themselves, either that cases of pneumonia are not recognized or are not reported with the completeness that prevails in the village group and in White Plains or that medical care in its broadest sense, including nursing service and facilities for hospitalization, is not as adequate. Possibly both are factors. It will be noted, however, that, in addition to the relatively higher mortality in the towns, the percentage of deaths from bronchopneumonia for that group actually exceeds the corresponding percentage for the villages in which both the population and the percentage of cases are much larger than in the town group. It does not seem probable that this preponderance of mortality in the towns could be due solely to incomplete case reporting.

The age distributions of mortality from bronchial and lobar pneumonias (Table IV) show the characteristic way in which

each form levies its toll with heavy concentrations of deaths from the bronchial form in the early and later years of life and with the larger percentages of deaths from lobar pneumonia in the four decades from 35 to 74 years. The most favorable age from the point of view of low mortality from both forms is the period from 5 to 24.

In this series of 1,011 deaths, 42 per cent were due to bronchopneumonia leaving 58 per cent caused by lobar pneumonia. Whereas the distribution by sex of the former was 52 per cent males to 48 per cent females, 56 per cent of the

Figure 7 Pneumonia as primary cause of death, county health district, 1931-1935. Duration of illness

deaths from lobar pneumonia were in males

The duration of the illness was tabulated from the death certificates for 355 fatal cases of primary bronchopneumonia and 493 fatal cases of primary lobar pneumonia. Of the former, 59 per cent of the deaths occurred during the first week of the illness and 19 per cent during the second week. For the lobar form the corresponding percentages were 66 and 23, respectively, thus indicating a shorter course in general for the latter. The distribution by days, of deaths occurring

during the first two weeks of the illness is shown in Figure 7 as percentage of total deaths for each form. The influence of selection is seen in the peaks that occur on the third, seventh, tenth, and fourteenth days. The tendency shown in these curves to a longer duration of the illness in the lobar form may be due to the more insidious nature of the onset in bronchopneumonia.

Of 714 deaths from bronchopneumonia, this form of the disease was assigned as a primary cause of death in 60 per cent and as a contributory cause of death in 40 per cent. This is, of course, in sharp contrast to lobar pneumonia which in a total of 642 deaths was given as a primary cause of death in 91 per cent and as a contributory cause in only 9 per cent. Separated by sex, pneumonia occurred as a primary cause of death more frequently in males by 55 to 45 per cent, while as a contributory cause the division between the two sexes is about equal. This is a reflection of the greater prevalence of lobar pneumonia among males.

Annual Rates

While the curves of morbidity and of mortality (Figure 8) both show a decided downward trend, the former has fallen to a somewhat greater degree than has the latter. During the period from 1922 to 1935 the morbidity rate decreased from 323 to 158, a drop of 51 per cent, while the mortality rate fell from 114 to 61, a decrease of 46 per cent. The peak in the mortality curve for 1918 was, of course, due to the epidemic prevalence of influenza at that time. These rates include both forms of pneumonia and, in the case of the morbidity rates, both primary and secondary infections whereas the mortality rates are for primary cause of death only.

The average annual morbidity rates were computed for certain subdivisions of the health district for the 1931-1935 period on the basis of the mid year population. According to these computations the rate for the district as a whole was 232, that for the city of White Plains, 240, and the rate for the rural area including the

Figure 8. Pneumonia death rates, county health district. Primary cause of death only both bronchopneumonia and lobar pneumonia.

unincorporated portions of the towns and five small villages, 201. There was a wide variation in the rates for the remaining nineteen villages ranging from 57 for Irvington to 480 for Mt. Kisco. The grouping of these villages by magnitude of rate is as follows:

| Rate | Number of Villages |
|---------|--------------------|
| 0-100 | 4 |
| 101-200 | 4 |
| 201-300 | 8 |
| 301-400 | 2 |
| 401-500 | 1 |

It is not possible from the available office records to determine a satisfactory fatality rate for pneumonia. As has previously been mentioned, the morbidity records include both primary and secondary infections with no way to distinguish between these two groups of cases. Pneumonia, especially of the bronchial form, occurs frequently as a secondary or complicating infection and thus contributes indirectly to the death rates of other diseases. While this is in itself of considerable importance, we are here more concerned with the fatality rate of pneumonia per se. Lobar pneumonia is known to occur most frequently as a primary infection and this is born out by the returns on the death certificates for that form of the disease. In only 9 per cent of the fatal cases in which lobar pneumonia was involved was it listed as a contributory cause of death. It would

seem, therefore, that a fatality rate for lobar pneumonia based on total reported cases (which include both primary and secondary infections) and total deaths (both as primary and contributory cause of death) would represent primary infections to so great a degree that a fairly accurate picture would be obtained of the death dealing propensities of this form as a distinct disease. Such a computation gave the following results by age groups

| Lobar Pneumonia | |
|-----------------|---------------|
| Age | Fatality Rate |
| Under 1 yr | 39 |
| 0-4 | 23 |
| 5-14 | 11 |
| 15-24 | 20 |
| 25-34 | 35 |
| 35-44 | 46 |
| 45-54 | 54 |
| 55-64 | 66 |
| 65-74 | 68 |
| 75 & over | 77 |
| All Ages | 40 |

The fatality rates for lobar pneumonia by sex were 39 for males and 41 for females in totals of 1,613 cases and 642 deaths

Prevalence of Types

During the period 1931-1935 the serum treatment of pneumonia was confined very largely to type I. Although serum for type II had been supplied by commercial laboratories for some time prior to that date, it was not made available by the State Department of Health until about January, 1937. Differentiation of type of pneumococcus was therefore limited very largely to the original grouping of types I, II, and III and a fourth group that included all pneumococci not belonging to one of these three types

| Year | I | II | III | IV* | Total |
|-------|-----|----|-----|-----|-------|
| 1931 | 25 | 14 | 27 | 104 | 170 |
| 1932 | 32 | 9 | 22 | 162 | 225 |
| 1933 | 41 | 6 | 21 | 125 | 193 |
| 1934 | 30 | 8 | 10 | 131 | 179 |
| 1935 | 25 | 7 | 16 | 153 | 201 |
| Total | 153 | 44 | 96 | 675 | 968 |

* All types other than I, II, and III

Typing examinations by the various laboratories for patients in the health district showed the foregoing results

But 16 per cent of the cases were of the type for which state antipneumococcic serum was available. The inclusion of type II cases for which commercial serum could be obtained would raise the percentage of cases that could have been treated with antipneumococcic serum to only 20. With serum now being supplied for additional types, the scope of the typing examination has been correspondingly extended and the possibilities of serum treatment increased.

One laboratory has reported examinations in 1934 and 1935 for types V, VII, and VIII with a total for these three types of only 18 cases out of a group of 135 representing types other than I, II, and III. Since state serum is now available for these additional types, the limited experience of this one laboratory (total of 166 positive examinations for the two years) would indicate that only about 30 per cent of the lobar pneumonia cases are of a type for which state serum is now being distributed.

The foregoing data suggest the inadvisability of becoming over optimistic regarding the results to be anticipated from the current campaign to promote the use of pneumonia serum. A good index of the effectiveness of our activities along this line would be the relative prevalence of the different types in fatal cases. This information for the health district is not now available. It is, however, some consolation to note in the above tabulation that type III, an especially virulent variety of organism for which an effective serum is not yet available, occurred in only about 10 per cent of the cases.

Use of Antipneumococcic Serum

There is no way of determining how many pneumonia patients received serum during the five-year period under consideration. The information cannot be got even indirectly since we know neither the amount of serum that was obtained from the commercial laboratories nor the average dosage administered.

The record of state serum distributed through the Westchester County Health Department which is the central distributing agency for the health district is as follows

| Year | Number Packages |
|-------|-----------------|
| 1931 | 13 |
| 1932 | 45 |
| 1933 | 14 |
| 1934 | 52 |
| 1935 | 47 |
| Total | 171 |

During these years the supply was limited to unconcentrated, type I serum put up in 50 cc packages

A comparison of the foregoing figures with the numbers of type I examinations previously given fails to disclose any obvious relationship between the two

Summary

1 Eighty per cent of a total of 3,178 cases were reported during the seven months from November to May with the largest number of reports falling in January. The peak of the mortality curve for each form is in January, also

2 Lobar pneumonia morbidity appears to be affected by seasonal changes to a greater degree than does bronchopneumonia.

3 The incidence of lobar pneumonia appears to be influenced by density of population, becoming greater with increased density

4 Of a total of 2,858 cases, 56 per cent were lobar and 44 per cent, bronchopneumonia. Of a total of 1,011 deaths, 58 per cent were due to lobar pneumonia and 42 per cent to bronchopneumonia

5 Whereas bronchopneumonia is evenly divided between the two sexes, lobar pneumonia is more prevalent in males. There is a similar distribution of deaths.

6 Bronchopneumonia occurs more frequently than lobar pneumonia under 5 years of age and at 75 years and over, the latter predominates from 15 to 44 years of age

7 The mortality from both forms is relatively greater in the towns (rural) than in the villages (suburban) or in White Plains (urban)

8 The larger percentages of bronchopneumonia deaths are in the early and later years of life, lobar pneumonia deaths are most numerous from 35 to 75 years

9 In fatal bronchopneumonia 41 per cent of the illnesses lasted more than one week and 22 per cent, more than two weeks. Corresponding percentages for fatal lobar pneumonia are 34 and 11, respectively

10 Bronchopneumonia was designated as a primary cause of death in 60 per cent and as a contributory cause, in 40 per cent of the deaths from that form. Corresponding percentages for lobar pneumonia are 91 and 9, respectively

11 From 1922 to 1935 the morbidity rate decreased by 51 per cent and the mortality rate by 46 per cent.

12 The average annual morbidity rate for the health district for the 1931-1935 period was 222 per 100,000

13 The approximate fatality rate for lobar pneumonia during 1931-1935 was 40 for all ages. It was highest (77) at 75 years and over and lowest (11) at 5 to 14 years. By sex the fatality rates were 39 for males and 41 for females

14 Not more than 20 per cent, at most, of the 968 cases for which results of typing examinations are available could have been treated with serum (I and II)

15 The numbers of patients treated with serum from 1931-1935 cannot be determined.

Pollution of the waters of the Hudson River valley by sewage from towns along its shores or on its tributaries is rapidly decreasing. Thirty communities now have sewage treatment plants

in operation and many more are under construction in the valley. Only fourteen communities along the Hudson and three on its tributaries have taken no action.

THE RESPONSIBILITY OF THE PHYSICIAN IN PREVENTIVE PROCTOLOGY

LOUIS A. BUIB, M D

(Section on Proctology, The Mayo Clinic, Rochester, Minnesota)

CURSORY investigation of the indices of medical publications reveals that on an average of at least once every two days in the past ten years a paper on the subject of diseases of the colon, rectum, or anus has appeared in some accredited medical journal. Further, at least once every week during the same period, an article on hemorrhoids has been published and 40 per cent of these articles have dealt with nonsurgical treatment. Many of these writings are fundamentally sound. Also, in some textbooks is given dependable material based on dependable experience. On the other hand, a great deal of what has been published has no value and some of it is productive of harm because the ideas presented, although erroneous, seem plausible.

There are many so-called practical manuals which deal with the treatment of hemorrhoids. Often they are short and easy to read and some of them present alluring schemes which the authors have developed after personal experience which they consider valuable. In some such manuals are found facts but in addition often there are descriptions of methods which may be productive of disaster. Some individuals who rely on such sources of information concerning proctology, after a few years' experience become imbued with the idea that they must limit their work to the treatment of "rectal" diseases. One such person wrote that all hemorrhoids could be cured by injection. Imagine what may happen when such measures are attempted by those who have had little or no experience. I venture to say that it is not by seeking the startling or bizarre but by attending to, and educating patients in, well recognized aspects of rectal and anal disease,

that the physician can contribute most to preventive proctology. Thought and effort expended on some of the minor anorectal disorders with which the succeeding paragraphs deal often will forestall serious illness.

The Patient's Complaint and Its Significance

The physician makes a troublesome error in handling the simpler types of anorectal disorders when he minimizes the significance of the disease. In the first place the problem appears much more significant to the patient and he may immediately regard the physician with suspicion, and besides, he is surprised later, when a throbbing pain sends him home and to bed. His disillusionment is complete if the wound becomes infected and days drag on before he is able to give full time to his business activities.

A patient may believe he has hemorrhoids and his grounds for this belief may be that he suffers with any one or any combination of the following conditions: backache, indefinite pain up inside the pelvis, constipation, general inefficiency and fatigue, insomnia, and so forth. The misfortunes of such an individual may be increased when hemorrhoids are found and removed without further search for the cause of the trouble. It never occurs to the patient, later, when his back still continues to incapacitate him, that it was his statement which implanted in the physician's mind the thought that hemorrhoids might be the cause of the backache. As a matter of fact, it is unfair to allow such a patient to go through an operation on the basis of his own belief as to what the trouble is. Usually it is some type of discomfort

Read by invitation at the Annual Meeting of the Medical Society of the State of New York, New York City, May 12, 1938

which brings the patient to the physician's office. Many times a patient who finds that something is wrong with his habits will pass the matter by, try to make the best of it, and wait to see what will happen. He may make use of some home remedy. When pain develops and he is unable to obtain relief from it he will usually consult a physician. It is in this particular that the physician is confronted by the most tragic circumstance. Due to the peculiarity of the nerve supply of the rectum, malignant lesions involving it never produce pain early unless they extend low enough to involve the tissues of the anus as well.

Patients may present themselves with a complaint of hemorrhoids, some have them but many have not. Both types may arrive at their conclusion because of the presence of blood and the physician is unpardonable who prescribes laxatives, ointments, or suppositories without first making the proper investigation. Even if the patient is examined superficially and it is found that he has hemorrhoids, and even if these hemorrhoids are found to exist in profusion, he should not be sent away until it has been determined, if possible, if a more serious lesion is lurking in the upper recesses of the rectum or lower part of the sigmoid. The obvious explanation must not be accepted until it can be proved that the other more serious possibility does not exist.

The physician should be on guard for the case in which a troublesome frequency of stool, accompanied by the discharge of blood and pus, is associated with a carcinoma of the rectum or sigmoid. This condition should of course be discovered by careful digital examination and a proctoscopic examination certainly will dispel all doubt. It is well known that patients who have rectal disease will defer consultation with the physician as long as possible and this is one of the chief reasons why proctologists are so handicapped in their attempts to deal with the cancer problem. Although bleeding, protrusion, and pain figure prominently as accompaniments of

hemorrhoidal disease, they are not always productive of enough inconvenience to cause undue concern. It is not surprising, therefore, to find that 32 per cent of our patients know of their trouble for at least ten years and that 80 per cent allow at least a year to elapse before coming for examination. When the significance of the lapse of a year in the development of a rectal carcinoma is considered, especially when the physical evidence of such a lesion begins only after it has reached a stage when it will bleed or produce signs of relatively advanced development, the importance of seizing the first opportunity to make a thorough investigation should be appreciated. It should be strongly urged that all patients who have symptoms referable to the rectal outlet be considered to have carcinoma until it is proved that such a lesion does not exist. If a patient would only greet the physician with the statement that he has cancer instead of hemorrhoids the physician would regard his problem more seriously and if the patient actually believed that he harbored a cancer he would come earlier and demand exhaustive examination.

One of every seventeen patients who come to the Mayo Clinic complaining of rectal trouble, has cancer of the terminal colon or anus, and one of every four of these patients who have cancer has received treatment for some other supposed rectal condition during the period of his chief illness, the cancer remaining undiscovered. This failure is owing to the attitude of the two chief parties concerned, namely, the physician and the patient, and can be corrected by the proper alteration of this attitude. It is difficult to convince the patient that as soon as he notices any peculiarity of function of his bowel he should consult his physician.

The Patient's Reluctance to Seek Examination and the Physician's Responsibility

The moment a patient is willing to present himself for the consideration of some disorder pertaining to the function

of the anus, rectum, or colon, he is entitled to most careful attention, the most significant part of which is thorough examination with the proctoscope

During proctoscopy, the physical and mental condition of the patient should be determined and efforts in his behalf should be modified by these factors. There are two circumstances of which the examiner may be sure, namely, either the patient has had a proctoscopic examination previously or he has not. In the latter instance he knows little of what will happen to him and the idea which he has formed of what is in store for him, gained either from his own imagination, or as a result of experiences which have been recounted to him by friends who have already been through the examination, leaves him in a confused and often skeptical state. Those who have already been subjected to proctoscopy seldom have had their co-operative abilities improved by the experience. Rarely one finds an individual who has neither been examined in this manner, nor has he any information regarding it. Success with this patient will depend on his nervous make-up, on the presence or absence of a pathologic condition, and on the capabilities of the physician. These factors, of course, apply to all types but the additional features just mentioned exert a significant influence. More rarely will the patient be that phlegmatic person who, knowing nothing of proctoscopic examination, also has no concern about it, and moreover harbors no pathologic or anatomic condition which makes painless examination impossible.

A physician should encourage those afflicted with rectal disorders to present themselves for examination as early as possible and teach them to be unashamed. They should be told of the painlessness of early rectal carcinoma and of the grave significance of the passage of blood before, during, or after defecation. Only in this manner will it be possible to lessen the period of uncertainty which is so costly and which many patients will

avoid if they know how. They neglect their condition because they do not realize its significance and because they possess a sense of modesty which should not be considered false. It is a characteristic which is possessed by many who have come under the influence of social refinement. They often fear medical attention, not only if an operation is required but even during an examination, and it is lamentable that their fears are often justified. They have learned the truth from those who have had similar conditions and have sought cures advertised in journals, circulars, and newspapers. They see a refuge in the glowing descriptions of the various "painless pile dissolvents" and "cures" of fissures, fistulas, papillae, prolapse and pockets, without the knife. There is a normal response when they embrace such measures and the physician should not be dismayed at the popularity of those who are the authors of such schemes.

I would not carry the impression that a proctoscopic examination as a rule is difficult to perform. Even the most experienced examiner may occasionally find himself involved in a series of "impossible" cases. This happens in all branches of medicine. However, if due consideration is given to the patient and if the examiner possesses the proper technical skill, nine out of ten proctoscopic examinations should be performed without difficulty. No prescribed technique can be followed during proctoscopy. After the salient anatomic features have been described and the psychologic factors have been discussed, practically everything else must be left to the capability and ingenuity of the examiner.

Too much consideration cannot be given to those factors which concern the attitude of the patient preceding, during, and immediately following an examination. It is surprising how important are the simplest little details and it is not unusual for the examiner's entire effort to be rendered useless by failure to observe some apparently inconsequential feature of the management of the patient.

Constipation, Hemorrhoids, and Laxatives

The proper function of one machine cannot always be considered a criterion of the normal functions of all. Some people are normally fat, others are normally thin and many people make a great mistake when they attempt to make their figures fit the dimensions and weights of some published chart. It is like this with the activity of the colon. Whereas it is generally considered normal for an individual to have one evacuation of the bowel each day, it is by no means unusual to find perfectly well persons who have a movement every other day or every third day, and sometimes even a week may elapse between defecations. Certain primitive people go a week or two, regularly, without emptying the colon, and there are authentic instances wherein patients have been known to go as long as a month, two, and even three months with no movement of the bowel. On the other hand, there are individuals who can be considered normal who have two or three stools a day. So that, in taking any history, it should first be ascertained what is the regular, normal bowel habit of that particular individual, or what it was before he considered it necessary to seek medical care, and then the physician should proceed to find out when and in what manner this habit has been altered.

The use of laxatives, or possibly I should say their misuse, probably is responsible for the development of hemorrhoids as frequently as any other single factor. When patent medicines are exploited by an array of competitive advertising organizations for purely commercial reasons, one who considers the present problem would shirk his responsibility if he should pass the subject without comment. The question as to whether hemorrhoids cause constipation or whether constipation causes hemorrhoids can be answered correctly by an affirmative response to either inquiry. By merely regarding the comparative ages of patients who have the two conditions, I feel that a significant clue is available. Hemorrhoids rarely

afflict youths, but constipation, especially among those who have trouble overcoming the habit, frequently begins in the early years of adolescence. Many persons begin the use of laxatives while in their 'teens' and often indiscreet parents give them laxatives while they are yet babies or young children. When these individuals reach adult years, often they cannot remember when they could get along without the use of some laxative, and many cannot remember ever having had a normal bowel movement. There are thousands of patented remedies and the baneful effect of many of them cannot be overstated. It is unfortunate that, in the constant endeavor to popularize use of his products and to increase his income, man deliberately will sacrifice the physical comfort and safety of his neighbor, by propaganda and misrepresentation.

Cleanliness in Health and in Disease

It would be desirable, were it possible, to establish a routine of personal cleanliness in regard to the care of the rectal outlet. There are few, even among the most refined people, who realize how inadequate are the methods usually employed in cleaning the part following defecation, and the task of correcting this is insuperable. If an individual will use any of the usual types of toilet paper after defecation and then will cleanse the parts further with a piece of moist cotton or gauze, invariably he will note a considerable residue of bowel discharge and fecal stain on the fabric. Probably healthy tissues are able to withstand any effect which might be produced by constant exposure to filth of this type, but it cannot be denied that when tissues are subjected to any strain which is sufficient to produce solution in their continuity, they will be rendered more vulnerable and much more likely to succumb to invasion by micro-organisms.

The application of active therapeutic measures begins with those simple methods employed to prevent the spread of infection in cases in which the crypts and papillae have, at the beginning, become

involved by mild inflammatory disease. In such cases an irrigation, or a small, warm enema of plain water or saline solution should be used daily following evacuation of the bowel. The purpose of this procedure is to cleanse the lower rectum and the anal canal in such a manner as to prevent their exposure to fecal discharges, therefore, the accumulation of large quantities of the solution in the lower colon should be avoided because, unless this precaution is taken, the peristaltic activity of the bowel will be stimulated and further evacuation of the colon will result. This will make an endless task of each session and, in addition, may produce irregularity in the bowel habit, which is undesirable. Patients can be carefully instructed regarding this part of the treatment, so that they can take care of it themselves while seated on the toilet, and by using a small, well-lubricated catheter they can move its tip back and forth within the anal canal, thereby cleansing the parts with little difficulty. Following this, they can lubricate the parts by applying a little white vaseline with the finger tip, covered with an ordinary finger cot, and often such treatment will suffice.

It may be advisable, in addition, to have the patient report each day, following such treatment, and he can then be assisted by irrigating the anal canal and lower rectum with an aqueous solution of metaphen, witch hazel, or some other suitable medicated solution. The physician should not merely prescribe ointments, or suppositories, to be applied by the patient himself, and expect a satisfactory result. It should be apparent that little can be expected in the way of relief, by the application of such medicaments, if they are administered in the presence of bowel discharges. If they are used, as is often the case, before the bowel is evacuated, they will only stimulate defecation and thus destroy any helpful effect which might have been produced had they been applied at the proper time. All medical types of treatment, thus outlined, should be accompanied by suitable examinations

in order to determine the response to treatment and in order to alter the character of treatment when necessary.

Complete and Incomplete Hemorrhoidectomy

Physicians should not follow old-fashioned schemes, without regard to the problems involved in any individual instance. It is said, for example, that hemorrhoids develop in three main groups—one on the left and two on the right side of the rectal outlet. It is said also, that hemorrhoids should be removed in three main groups, "being sure to leave a strap of mucous membrane" between the points where the hemorrhoids were removed. The caution also has been given that these three straps should represent no less than a third of the circumference of the anorectal outlet, in order to avoid the development of stricture, but the ever-present group of post-operative marginal external tags and deformities proves the faithfulness with which such teachings have been observed. It might have been better if such methods never had been taught because we are still operating on patients who underwent hemorrhoidectomy thirty years or more ago and, worse than that, we are operating on patients who have had these obsolete methods applied to them more recently.

It should be understood that by careful technic and the proper regard for sound principles in the care of infected wounds, all of the hemorrhoids can be removed without producing undesirable distortion or disturbing the function of the parts. Following a properly performed hemorrhoidectomy, hemorrhoids will not recur and it is only when all hemorrhoids have not been removed that they do recur. The surgeon's fear of causing stricture is the reason why, in some cases, hemorrhoidectomy is incomplete and when operation on some of the more complicated types of hemorrhoids is considered, it is easy to understand why inexperienced persons should entertain this fear. However, experience has proved that such fear is unfounded if the

operation is properly performed and if the parts remain in place, as they were at the conclusion of the operation, undisturbed by the sloughing which complicates wounds which do not receive proper attention.

Prerequisites to General Improvement in Proctologic Work

The medical profession has discharged well its duty to the public, and to point out something that needs further attention by members of the profession is not to condemn the profession or to minimize its efforts. Nevertheless, to some physicians it has been a matter for boasting that they cannot be bothered with 'rectal cases', to many more it has been a matter of regret. As long as some members of the medical profession are willing to pass lightly over rectal problems, they may expect those who employ business methods in medical practice to flourish.

Whenever a patient with rectal trouble consults these so-called charlatans, the utmost consideration is given to the problem presented. The experience of many such practitioners is broad and their skill in conducting examinations and administering treatment is often better than that of many who shun them. Therefore, as physicians review the history of medical practices and observe the type of rectal surgery that has been

approved by some legitimate surgeons, when they consider the lack of equipment for diagnosis and treatment of anal and rectal disease which some of their colleagues possess, when they consider the indifferent attitude toward anorectal disease of some who are at the head of hospitals and teaching institutions, and when they realize the horror of "pile," fissure, and fistula operations, which has been passed on from one generation of laymen to another, the evils should be recognized and knowledge gained which should reveal the remedy.

This remedy will come only through a proper alteration in the present attitude of the representative men in the medical profession. Those who have ability must interest themselves sufficiently in this type of work. Some should do the work as a part of their general practice or as a part of their duties as internists and surgeons, some should go a step further and carry on this work more intensively, while others should limit their work to proctology and proceed not only to care for patients but to seek to increase the facilities for the teaching of proctology both in undergraduate and in postgraduate institutions. Most of all, it is necessary that those who are at the head of hospitals and teaching institutions give opportunity to those who are interested in the work and are ambitious to help with its advancement.

MYSTERIOUS HUMAN BAROMETERS

A St. Louis doctor has a patient who predicts rain accurately everytime' by a severe attack of insomnia about twenty four to twenty-eight hours before the storm. Many people and animals exhibit this mysterious excitability and irritability as storms approach remarks the J.A.M.A. Some believe that a real tissue swelling occurs as outside pressures are reduced and the cells imbibe free water from their surrounding medium (much as does a sponge). Many people have a severe headache, which is relieved as soon as the pressure begins to rise again. Some others with sclerotic changes exhibit a distinct tendency to convulsions and unconsciousness during periods of rapidly declining pressure.

POSTGRADUATE SCHOLARSHIPS

The New York Postgraduate Medical School Columbia University has a scholarship fund which is available for qualified graduates in medicine who wish to take postgraduate courses at this school.

THE PROGNOSIS OF INSURED NEUROTICS

A Study of 1,000 Disability Insurance Claims

PETER G. DENKER, M.D., New York City

(Assistant Visiting Neurologist, Bellevue Hospital)

IT is probably true that "psychoneurosis" is the most frequently made diagnosis in medical practice. Culpén and Smith,¹ in a routine examination, found that about 50 per cent of factory workers, and 70 per cent of students had neurotic symptoms, 16 to 20 per cent of these symptoms being of fairly severe degree. Cassidy,² in his consulting cardiologic practice, notes that 29½ per cent of persons seen by him are neurotic and show no evidence of organic heart disease, and this estimate is even exceeded by Houston,³ who believes that at least half of these patients presenting themselves as suffering from heart disease are cardiac neurotics. Of 2,000 consecutive ambulatory cases in the Boston dispensaries, 45 per cent were psychoneurotic⁴ and Lockhart, quoted by Gillespie,⁵ would have us believe that "as much as 60 per cent of the time lost through sickness in certain industries is lost through psychoneurotic illness of some kind or another." The neurosis is not only frequent but is often prolonged in its course. Thus, Halliday,⁶ as Regional Medical Officer for Scotland under the Insurance Acts, found that one-third of 1,000 patients referred to him due to prolonged incapacity, and supposed to be suffering from organic disease, were in fact ill from neurosis. All these patients were rechecked by specialists and an independent observer. Similarly, Hoare,⁷ in his analysis of the disability claims of the Penn Mutual Life Insurance Company found that next to diseases of the heart, the most frequent cause of disability was disorder of the nervous system, constituting 16 per cent of their claimants. It is interesting to note that the claim of longest duration

(twelve years) in his series was due to a neurosis resulting from a fracture of the skull. Furthermore, in an analysis made according to duration of illness, the cases due to nervous system disease were found to constitute 40 per cent of the total number of claims, in this respect leading the field by a large margin. The economic loss to the individual and to industry due to this impairment is, therefore, obviously severe.

Outline of Study

It was thought that a follow-up study of 1,000 consecutive disability claims due to psychoneurosis might add some enlightenment to this complex problem. These claimants were all insured in the Equitable Life Assurance Society of the United States, and if totally disabled received varying amounts of money in monthly payments depending on the amount of insurance carried. Most of these policies were issued between the years 1915 and 1930, the inception of their disability occurring from one to twenty years after issue. The diagnosis in all instances was made by a physician and often corroborated by a nerve specialist or psychiatric hospital, and in the New York area most of the cases were personally examined by the writer. Total disability was only recognized after the insured had been ill for at least three months and to an extent that would prevent him from engaging in any occupation for remuneration or profit. The milder or more transient neurotic disturbances are, therefore, automatically excluded from this study. Lastly, the follow-up study was made at least five years and, in many cases, ten to fifteen years

This paper was read before the Association of Life Insurance Medical Directors on October 29, 1937

after disability had commenced results being obtained by correspondence with the insured or his physician, examination by the Society's examiners, personal interviews or inspection reports. Due to the co-operation of these various informants, 100 per cent of the cases were traced and brought up to date.

Great Frequency of Error in Diagnosis

The great risk of error in too glibly labeling a patient a neurotic was apparent early in the study. On following the cases it was found that 293, or 29.3 per cent of the total 1,000 cases had been erroneously diagnosed as "psychoneurosis," the true nature of the illness manifesting itself in most cases within one year, as some organic disorder. There were 62 deaths in this group of 293 cases, an unusually high percentage. It is interesting to note that in a follow up study of 100 patients diagnosed as "neurosis," Comroe⁸ found that 24 per cent showed definite evidence of organic disease within an average period of eight months, never after two years, figures closely approximating ours. In most instances rechecking of the original hospital records of these patients revealed that symptoms suggesting the organic disease were present during the original admission. He likewise experienced a high mortality rate, 7 of the 24 cases dying within two years. A tabulation of these 293 cases erroneously diagnosed neurosis follows.

TABLE 1.—END RESULTS OF CASES ERRONEOUSLY DIAGNOSED NEUROSIS

| | |
|--|-----------------|
| 1. Psychosis (manic-depressive schizophrenia, involutional melancholia, general paresis, etc. (suicides, 20) | 149 |
| 2. Cerebral arteriosclerosis and hemorrhage | 21 |
| 3. Other organic brain disease | 25 |
| 4. Pulmonary tuberculosis or lung abscess | 17 |
| 5. Organic cardiac disease | 13 |
| 6. Hypertension and nephritis | 14 |
| 7. Cancers | 7 |
| 8. Cholecystitis or cirrhosis of liver | 8 |
| 9. Duodenal ulcer | 4 |
| 10. Chronic arthritis | 7 |
| 11. Miscellaneous | 28 |
| | <hr/> 293 cases |

It cannot, therefore, be too frequently emphasized that the pitfalls in diagnosing a "neurosis" are deep and that the diagnosis should only be made after a most meticulous exclusion of organic disease has been carried out. It would probably be wise not to insure an individual for at least six months to one year after recovery from a neurosis.

It might be appropriate at this point to mention the extreme difficulty which is occasionally encountered in differentiating between the neurotic and the malingerer. The malingerer realizes he is not ill and consciously simulates his symptoms, whereas, the neurotic is genuinely convinced that he is sick and is usually unaware of the emotional factors related to his difficulties or the purpose that his symptoms are serving. The inconsistencies in history and examination, as well as the frequent exaggeration of symptoms or signs by the malingerer, help in diagnosis. To make matters more difficult the two conditions may coexist. Foster Kennedy⁹ has aptly described this state, "hysteria and malingering are often dovetailed and come together in one mind, and many symptoms begun as malingering end as hysteria by suggestion. In the great majority of cases, one cannot tell easily what is virtue and what is vice. Just as few of us know if we are all good or all evil, we are in truth neither black nor white, just gray."

The remainder of this paper will concern itself with an analysis of the 707 true neurotics in this series.

Age

The age of onset encountered in the study varied widely from 19 to 59 years, the average age being 37.2 years. This is in contrast to the slightly higher age average of the erroneously diagnosed group in which 40.8 years was obtained. The chances of error in diagnosis is, therefore, somewhat greater at the higher ages. It would seem that middle age in the male produces the greatest neuroses, possibly because his responsibilities are greatest and his career made or broken at this period. In the female this age inci-

TABLE 2—AGE AT ONSET OF DISABILITY

| AGE AT ONSET | MALE | FEMALE | BOTH SEXES |
|--------------|------|--------|------------|
| -10 | 2 | | 2 |
| 20-24 | 17 | 38 | 55 |
| 25-29 | 43 | 61 | 104 |
| 30-34 | 64 | 82 | 146 |
| 35-39 | 67 | 55 | 122 |
| 40-44 | 75 | 33 | 108 |
| 45-49 | 57 | 30 | 87 |
| 50-54 | 39 | 19 | 58 |
| 55-59 | 20 | 5 | 25 |
| Total | 384 | 323 | 707 |

dence is somewhat lower. As Halliday⁶ puts it "he tends to look before and after and pine for what is not, and by means of an illness escapes the responsibilities of an immediate or future environment hard to contemplate steadily." Burns expressed the mood when he wrote, "But, oh, I backward cast my ee on prospects drear,
An' forward tho' I canna see, I guess and fear."

Sex

Of the 707 cases, 384 were males and 323 females. Forty-five per cent of these claimants were, therefore, females, as contrasted to the fact that only 12-14 per cent of the insurance policies during these years were held by women. Neuroses were, therefore, 3 to 4 times as frequent among females as male insureds, which corresponds with the clinical frequency of female neurotics. Of 100 neurotics studied by Bennet and Semrad,¹⁰ 73 per cent were females and 27 per cent males, and 61 per cent of Luff and Garrod's¹¹ series were females.

Occupation

Occupationally claimants might be classified roughly as follows:

TABLE 3—OCCUPATION OF DISABILITY CLAIMANTS

| | |
|----------------------|-----|
| Clerical workers | 185 |
| Executives | 170 |
| Teachers | 132 |
| Merchants | 88 |
| Professional workers | 54 |
| Farmers | 33 |
| Nurses | 23 |
| Students | 13 |
| Manual workers | 7 |
| Housewives | 2 |
| | 707 |

No definite conclusions can be drawn, but the high incidence among clerical workers, executives, teachers, and professional people contrasts forcefully with the greatly diminished number of manual workers and housewives. On looking over the case histories, one was often struck by the monotonous existence of the occupational misfit, the clash of temperament and intelligence, etc. "Blessed is he who has found his work, let him ask no other blessedness," wrote Carlyle, and Huddleson¹² has worded the problem well "whatever his personal and family histories have been, any individual may find himself in a situation that tends to become progressively more unbearable and so predisposes to psychoneurotic conduct. A man working at tasks beyond his intellectual or physical capacity, or his emotional endurance, and harassed by obligations to carry on exhausting work without being able, from whatever ultimate maladjustments, to derive satisfaction from his work, this man is becoming predisposed toward a neurosis. Bare failure is intolerable, but failure camouflaged and compensated for by an illness that brings attention, sympathy, rest, and often an indemnity or wages without work is far from intolerable."

Family or Past History of Mental Disease

Though a history of familial mental taint is frequently obtained in the private neurotic patient, such a history was only rarely given in this series. Thus, there were only 45 individuals of the 707 who presented a history of nervous or mental disease in either themselves or their family, an incidence of about 5 per cent. Yaskin¹³ in a review of 100 psychoneurotics obtained a positive family history of neuropathy in 60 per cent. This discrepancy is probably explained by the absence of a special question on the insurance application as to mental disease in the family, as well as by the fact that the average insurance examiner is not neurologically minded. Lastly, lack of candor

on the part of the applicant plays an important role

Life Expectancy

A thorough search of the literature revealed no accurate mortality study of people who have suffered from a neurosis. The following table expresses our experience in this series of 707 cases

TABLE 4—MORTALITY STUDY OF NEUROTICS

| ATTAINED AGE | ACTUAL DEATHS | MALES EXPECTED DEATHS | | MORTALITY RATIOS | |
|--------------|---------------|--------------------------|-------------------|------------------|-------------------|
| | | U. S. Table | E. L. A. S. Table | U. S. Table | E. L. A. S. Table |
| -39 | 4 | 5 30 | 3 42 | 75% | 117% |
| 40-49 | 5 | 9 62 | 7 13 | 52 | 70 |
| 50-59 | 8 | 12 08 | 10 06 | 57 | 62 |
| 60 | 1 | 3 70 | 3 65 | | |
| | 18 | 30 76 | 25 16 | 50% | 72% |

| FEMALES | | | | | |
|---------|---|-------|-------|-----|-----|
| -39 | | 6 24 | 4 62 | | |
| 40-49 | 2 | 4 48 | 4 28 | | |
| 50-59 | 1 | 3 83 | 4 62 | | |
| 60 | 1 | 71 | 87 | | |
| | 4 | 15 25 | 14 39 | 26% | 73% |

This study was made from the inception of the disability to the date as of which we were last able to trace them. There was a minimum of at least five exposure years for each case, with a total of 2,981 exposure years for the 384 male cases and 2,526 years for the 323 female lives. The average number of years of follow up was, therefore, 7.6 years. The expected deaths were calculated by three mortality tables: (1) a table representing the Society's own experience between 1928 and 1932 on standard insurance policies in force more than ten years (this was applied to both the male and female experience), (2) the U. S. White Males Table representing the experience during the period 1928-1931 of the total white male population of the continental U. S., and (3) the U. S. White Females Table corresponding to the Males Table. Each of these two tables was applied to the

corresponding sex in this present study.

There was a total of 18 male and 4 female deaths in the entire series, death being due to various causes. The expected number of male deaths was 30.76 deaths according to the U. S. Table and 25.16 deaths in the Equitable Life Assurance experience, giving a favorable mortality ratio for the entire male group of 50 per cent and 72 per cent, respectively. In the female group only 4 deaths were experienced, giving a mortality ratio of 27 per cent. It is, therefore, evident that psychoneurotics have a life expectancy which is better than normal. This is probably due to the excessive care and pampering they usually undergo, their escape from the winter rigors to southern climates, long vacations, frequent rest periods, etc. There would thus seem to be statistical proof for the opinion that neurotics are more likely to wear out their families and friends rather than themselves.

A word as to the frequency of suicide among neurotics. Though the fear of committing suicide is a frequent symptom in patients suffering from anxiety states, and hysterics often threaten to do so, the risk of a person committing suicide who is suffering from a true neurosis is very small, and the old saying that these patients are too fond of themselves for this to be a serious risk is a true one. In the 22 deaths in this series there were 3 suicides. Jamieson¹⁴ in a study of 100 suicidal deaths found only 4 in psychoneurotics, these were in the acute phase, with morbid fears, depression, and various hypochondriacal symptoms resembling a mixed manic-depressive reaction. It is interesting to note that over two-thirds of his 100 cases occurred in the course of a psychosis of the manic-depressive type. T. A. Ross,¹⁵ in an experience of over 1,000 cases of neurosis, encountered only 7 suicides, once again the accuracy of diagnosis must, therefore, be stressed. The psychoneurotic should be carefully differentiated from the psychotic. The small suicide hazard in the neurotic is in marked contrast to the much greater risk of this tragedy in the psychotic. Strecker

TABLE 5—MONTHLY DISABILITY INCOME GROUP

| DURATION OF DISABILITY | ALL CLAIMS Percentage | WAIVER ONLY Percentage | LESS THAN \$50 Percentage | \$50-\$99 Percentage | \$100-\$199 Percentage | \$200 Percentage |
|------------------------|--------------------------|---------------------------|------------------------------|-------------------------|---------------------------|---------------------|
| Less than 1 year | 45.4 | 31.6 | 47.4 | 43.4 | 45.8 | 41.9 |
| 1 year or more | 54.6 | 68.4 | 52.6 | 56.6 | 54.2 | 58.1 |
| 2 years or more | 27.4 | 36.8 | 25.0 | 30.2 | 23.6 | 35.6 |
| 3 years or more | 18.3 | 26.3 | 16.8 | 18.7 | 16.7 | 25.8 |
| 4 years or more | 14.0 | 15.8 | 12.2 | 14.8 | 12.5 | 24.2 |
| 5 years or more | 10.3 | 15.8 | 8.2 | 11.0 | 8.3 | 22.6 |

and Palmer¹⁰ have clearly differentiated the two, "a psychoneurosis is essentially different from a psychosis. The psychotic is profoundly shaken in his whole personality and sometimes disintegrated, there is a deep cleft between self and environment, and reality for him is disturbed, distorted, and even abolished. In the neurotic there is only a partial personality altering and environmental contacts remain real and relatively undisturbed. Meyer sees the psychoneurosis as part reactions, halfway places between normal and psychotic, maladaptions to be sure, but, nevertheless, compromises that recognize and concede the claims of reality. Finally from the standpoint of insight, the capacity to 'stand off' and 'look in,' survey and judge, even if not understand, here the psychoneurotic overwhelmingly demonstrates his freedom from the psychosis."

Duration of Neurosis

Of the total of 707 cases

- 45.4 per cent terminated within 1 year of onset
- 27.2 per cent terminated during 2nd year
- 9.1 per cent terminated during 3rd year
- 4.3 per cent terminated during 4th year
- 3.7 per cent terminated during 5th year
- 10.3 per cent were still disabled 5 years after onset.

Approximately three-fourths of all cases, therefore, recover within two years of the onset of disability and a little less than

half within the first year. In the follow-up series of Luff and Garrod,¹¹ three years after the patients had been discharged from the clinic, 55 per cent were found to be in good health, the results being more or less identical for all therapeutic methods used, including analysis. In our series, 20 cases had been treated by lengthy analysis with approximately the same degree of success as the remainder of the cases treated according to various other procedures, making one doubt the peculiar therapeutic efficacy of this procedure. Yaskin¹² in his series of 100 neurotics, found that 41 recovered, 41 improved, and 18 had not been benefited by treatment in hospital or clinic. He likewise felt that for most of the patients, suggestion, encouragement, medication, and partial analysis of the precipitating conflict was sufficient.

It was thought interesting to attempt to ascertain if any relationship existed between the amount of disability income and the duration of the illness. The table above shows the persistency of these claims over a five-year period from the initial date of the disability, expressed on the basis of percentage of the total claims in each category.

It can readily be seen that in the higher disability income brackets the duration of the claim is likely to be longer. Thus, whereas only 10.3 per cent of all claims lasted five years or more, in the disability income group receiving \$200 or more per month, 22.6 per cent of the cases lasted this length of time. Furthermore, it would seem that after the third year in this higher income group the percentage remains almost constant, so that it is fair to say that neurotics receiving \$200 or

more per month, who have been ill for three years, practically never get well. It would seem that the monthly disability check eliminates the incentive to get out and fight life's struggles, and, in addition, it acts as a constant reminder to the highly suggestible, mentally ill patient that he is disabled, and an invalid, and recognized as such by the outside world. Instead of helping to rehabilitate the neurotic, we are doing the worst thing possible for his mental health, constantly impressing upon him that society looks upon him as useless and unable to carry on. How much wiser we would be, to pay these claims by some form of lump-sum settlement at the end of the first year of disability or sooner.

Lump-Sum Settlements

In the last few years, much has been written pro and con about 'lump-sum settlements.' In Denmark, compensation is paid in a lump sum at an early stage of the incapacity and 93.6 per cent of the injured recover from what in this country would be called a traumatic neurosis. On the other hand, the sick man in Germany is entitled to a monthly pension and only 9.3 per cent recover from the same disease.¹⁷ Jolly¹⁸ has had a similar experience with industrial hysterics, finding the percentage of cures high when lump-sum settlement is speedily made, whereas it is low where the individual draws weekly compensation. Foster Kennedy⁹ quotes Dr. Lewy, who is chief medical examiner for the compensation commission of the State of New York as saying that he has 'never known of a single case from my very large material, which was ever disposed of, unless the individual received a monetary remuneration to his own satisfaction.' Norcross,¹⁹ on the other hand, in a follow up study of compromise agreements, settled by lump sum in New York State, found the system used did not produce successful results, in that, in most cases, the claimant's physical health or mental attitude was not improved, nor did it stimulate him to find work or aid in the conservative expenditure of his compensation

money. Marked improvement resulted from the settlement in only 17 of 64 cases. He attributes most of the failures to unnecessary delay in the compensation process, extended litigation and unwise handling of these cases by the insurance carrier or their representatives. "The group which understands this type of man best, namely the State Compensation Medical Staff, often makes recommendations which are not followed. He recommends that the interval between the onset of neurosis and the settlement should be shortened, investigations should be speeded up, and neurotic claimants should not be given copies of their medical reports or hear medical testimony which might cause them further anxiety or worry. They should not be advised that it is legally possible to reopen their cases at a later date if their conditions change for the worse, since such knowledge is harmful to the neurotic patient. 'Work of any kind is the best therapy,' and better co-operation from the insurance companies would return more claimants to work much sooner."

The medical literature is full of warnings about the futility of closing neurotic cases a long time after the accident. Though writers differ as to the manner in which claims should be settled, all agree they should be settled promptly and be rather small, and that prolonged litigation and appeals are the worst things that can happen to a psychoneurotic. All the emphasis is on *early* closure. Huddleson¹² writes: 'If the final settlement is delayed for a number of months, the neurosis is not immediately alleviated by the indemnity and may become quite unaffected.' Sir John Collie²⁰ refers to the protracted legal delays relevantly by saying, 'In cases which are contested the "Law's Delay" accounts for a great deal of prolonged disability, and the development meantime of functional disease. The close questioning, often repeated, as to the exact details of the accident and his feelings by both lawyers and doctors and the everlasting inquiries of well meaning but injudicious friends and acquaintances, all help to rivet the man's atten-

tions on his internal anatomy Too often his abnormal mental condition will remain until the dispute arising from the accident is settled, and generally, so far as recovery is concerned, it matters less than one would expect whether the claimant wins or loses" An educational campaign whereby the legal profession, insurance adjustors, and legislative arbitrators and physicians could grasp the conception of neurosis, and learn to realize the advantages the neurotic obtains by being ill would go a long way toward intelligent handling of these cases

In this series, 15 claims were settled by compromise and lump-sum payment, usually this included the repurchase of the disability clause by the Society In 5 of the 15 cases, no clear-cut opinion could be rendered as to whether or not benefit had been obtained by this form of procedure Seven cases, however, were followed by distinctly favorable results, the patients recovering rapidly and remaining in good health for a long period of years In the 3 remaining cases, no beneficial effect was obtained, the disabling neurotic symptoms persisting for long periods following settlement. An attempt was made to analyze the reasons for the success in some cases and failure in others, and the following table lists the results in those cases where a definite opinion could be offered

TABLE 6

| CASES SUCCESSFULLY TERMINATED BY LUMP SUM | | |
|---|--|--|
| AGE AT ONSET OF DISEASE | DURATION OF DISABILITY BEFORE SETTLEMENT | AMOUNT OF DISABILITY INCOME RECEIVED |
| | No of Years | Monthly |
| 28 | 5 | \$ 50 |
| 33 | 1 | \$100 |
| 29 | 2 | \$500 |
| 31 | 1½ | \$ 50 |
| 33 | 1½ | \$400 |
| 43 | 1½ | \$840 |
| 37 | 6 months | \$250 |
| CASES UNSUCCESSFULLY TERMINATED BY LUMP SUM | | |
| | | |
| 44 | 3 | \$100 |
| 48 | 4½ | \$ 65 |
| 42 | 3 | \$250 |

It is clearly seen from the above tabulation, that (1) cases in the younger age groups (roughly under 40) are more favorable for lump-sum settlements, and (2) the shorter the duration of disability before settlement is made, the better the outlook of success It would also seem from the above that the amount of disability income is not as important a factor as are the two previously mentioned A claimant receiving \$840 a month, who had been ill for one and one half years, was promptly cleared up of mental symptoms by settlement of the case in one sum, and was soon back at work functioning normally Experiences of this type make one feel that the situation with the disabled neurotic is far from hopeless, and that intelligent handling of this form of disability could go a great way toward minimizing the severity of the problem

Summary

1 A follow-up study of 1,000 consecutive disability claims for psychoneurosis was made, at least five years after disability had commenced

2 Almost 30 per cent were found to have been incorrectly diagnosed, the true nature of the illness manifesting itself within one year

3 A mortality study of the series shows that neurotics have a distinctly greater life expectancy than normal The rarity of suicide in this group is stressed

4 The duration of neurosis in relation to disability income, type of therapy, age, sex, and other factors is discussed

5 The cases settled by lump-sum compromise are analyzed, and this method of terminating neurotic claims is reviewed in the light of our experience as well as others

SOCIALIZED MEDICINE IS BAD BUSINESS TOO

A strong letter has been sent by the Bronx Chamber of Commerce to the two U S Senators from New York State and to the three Bronx members of Congress expressing opposition to certain phases of the Administration's Health Program. It is based on sound reasons that would appeal to all business bodies and runs thus:

"While thoroughly sympathetic with any welfare measures that may be promulgated in the interest of the general health of our community it is not difficult to realize that under present economic conditions any attempt on the part of the Federal government to launch a compulsory health insurance program estimated to cost \$350 000 000 per year for ten years, with an ultimate cost of approximately close to \$2 000 000 000 would constitute a boomerang so far as general conditions are concerned. It certainly would increase both direct and indirect taxes which are already bordering on being unbearable, and it would likewise lead to greater invasion of private enterprise by the Government.

In expressing our position, we should like to

point out that the medical fraternities in various States including this one are working out plans for professional attention similar to that now available under the hospitalization plan which costs three cents a day which would be supplemented by medical care for an additional two or three cents a day. Under such an arrangement all persons with a stated income would be able to insure themselves so as to be free from worry of fees for doctors, laboratory examination, hospital charges and other considerations which go to make up a health insurance program.

Those in the lower brackets of income would of course have to be taken care of through the regular public hospital facilities. It would seem common sense for the government to encourage this type of social security in which everyone who can afford to will pay rather than embark upon further tax burdening projects.

It is earnestly requested that you be guided in your deliberations by the facts presented herein and which we believe will be accepted as sound and desirable for the best interest of the greatest number of our people."

A TIP FROM THE SIDELINES

They say the looker-on sees most of the game, and some of the comments by press writers on socialized medicine reveal how it looks to the man on the fence." Thus a writer in the *New York Daily News* after summarizing the points for and against, gives a tip to the medical profession. He says:

What all the doctors had better bear heavily in mind, we think, is this: That if they don't get together and agree to support one or more forms of doctor-controlled collectivized medicine, the politicians may take the whole play away from them.

The President is expected to lay a huge national health scheme before the coming Congress. It is a fact that too many Americans get too little of the medical service that is now available or could be made available, and that more and more people are coming to demand adequate medical care as a right.

It looks as if the only choice left to the doctors is whether to run some expanded public health system intelligently and expertly or to be themselves run by a lot of politicians and social service workers trying clumsily and ignorantly to make an expanded public health system work.

HEART DISEASE AND PREGNANCY

R CARMICHAEL TILGHMAN, M D

(Assistant Visiting Physician, Medical Consultant to the Division of Obstetrics, The Johns Hopkins Hospital, Baltimore, Maryland)

THE LATE Sir James Mackenzie, the great Scotch cardiologist and physician, who was keenly interested in the behavior of the heart during gestation, opened his book with these words "There are few subjects in medicine of which an accurate knowledge is more urgently required than that of a woman's fitness for childbearing." It is at once apparent that the physician, in expressing his opinion on this point, must perforce have an exact knowledge of the status of heart, for the burdens of pregnancy on the circulation are great ones. Only too often does the extra work resulting from the pregnancy amount to more than the heart can do, and the final outcome is disastrous.

The problem of handling the pregnant cardiac patient is not an easy one. It is not one to be decided by the obstetrician alone or by the internist alone. The best interests of the patient are served by the combined effort of the two. At The Johns Hopkins Hospital an attempt has been made to solve the medical difficulties arising in the course of pregnancy by appointing a medical consultant to the department of obstetrics. One of his duties is to visit the obstetrical outpatient department on a regular day for the specific purpose of discussing with the obstetricians the management of their medically complicated cases. In this way the problem can be threshed out *in situ*, and the plan of the follow-up care of the patient be determined. The nature of the complication is the deciding factor governing the frequency of the return visits. Some patients are seen weekly, while a monthly visit may suffice for the care of others. If the condition is grave or puzzling, the

patient is admitted to the obstetrical wards for further medical and obstetrical study.

An opportunity, therefore, has been afforded for close personal observation of a number of cardiac patients registered in the obstetrical dispensary of The Johns Hopkins Hospital. The content of this paper has been based to a large extent upon the study of this group of patients.

Although some women present themselves to their physicians for the deliberate purpose of obtaining an estimate of their physical fitness to bear a child, this occurrence is comparatively an infrequent one. This is especially true of the dispensary type of patient. The vast majority of complicated cases are seen by the doctor after the pregnancy has become a reality and in many instances after two, three, four, or more months. By this time the physiologic influences of the pregnancy itself upon the general condition of the individual and especially upon the circulation have probably made themselves manifest, and the diagnosis of organic heart disease as well as the plan of care are frequently rendered very difficult.

If a pregnant patient is suspected of having a cardiac abnormality it is obviously desirable and indeed necessary to establish this fact as early as possible. In making a definite diagnosis, the clinician must take cognizance of the physiologic changes *per se* occurring with pregnancy, lest he be led into serious error. What, then, are some of the changes influencing the cardiac status that one observes in pregnant women?

One feature that occurs with great regularity during pregnancy is the simple

gain in body weight. Even laymen are perfectly familiar with the puffing and blowing exhibited by the fat woman when she exerts herself. The addition of some twenty pounds or more during pregnancy may often be an adequate explanation of the dyspnea and fatigability complained of by certain obstetrical patients. One must not be too hasty in accepting a history of exertional dyspnea as an indication of circulatory insufficiency.

It must be the rare case in which the diaphragm is not elevated due to upward pressure exerted by the enlarged uterus. In determining the size and position of the heart, whether by percussion or by teleo-roentgenogram measurement, it is of the utmost importance to know the extent of the abdominal distention before deciding that the heart is enlarged. Moreover, the effect of the upward pressure of the elevated diaphragm does more than cause a simple lateral displacement of the heart, the heart is also twisted and rotated, a feature of importance that will be discussed later.

Moreover, the enlarged uterus does more than raise the diaphragm. There is the direct pressure exerted upon the iliac and pelvic vessels. In the normal non-pregnant subject, the venous pressures in the arm and in the leg are approximately identical. If one compares the venous pressure readings taken in the femoral veins with the readings in the antecubital veins in the normal pregnant woman, one will find the arm vein pressure to be quite normal whereas that in the femoral vein is usually 100 to 200 mm. of water higher than in the arm, i.e., from two to three times normal.

In many patients the result of the increased venous pressure in the legs, with the stasis in the pelvis (the latter on a purely mechanical basis) is the production of edema of the feet and ankles. Again, then, the observation of dependent edema does not suffice to establish this occurrence as having pathologic significance.

Aside from these purely mechanical effects of the gravid uterus, there are demands made upon the circulation and the

normal heart. The circulatory adjustment during pregnancy must compensate for the following:

1 Pulse rate—this is usually elevated some ten to twenty beats per minute.

2 Arterial blood pressure—there is an increase in the width of the pulse pressure, so that the pulse feels more collapsing, and this change is due to a decrease in the diastolic level to an extent slightly more than the decline in the systolic pressure.

3 Circulation rate—this is variable during the different stages of the pregnancy, but on the whole there is a slight speeding up of the circulation.

4 Vital capacity—there is no significant change.

5 Oxygen absorption—the total oxygen absorbed by the maternal lungs is increased, usually nearly 15 to 20 per cent above the nonpregnant level.

6 Total blood volume—this is increased in some cases as much as 40 per cent.

7 Cardiac output, i.e., the minute volume output of the heart—this increases frequently 50 per cent above normal from the fourth to the eighth month and during the last month may return to the normal level or it may remain elevated for four weeks after delivery.

From the foregoing then it is apparent that one may expect several physiologic physical signs to appear during the course of the pregnancy, which, without adequate knowledge of the normal pregnancy changes, would lend confusion in making a diagnosis of organic heart disease. Perhaps the most important of these physiologic physical signs is the occurrence of a systolic murmur. Various observers have estimated that it is present in from 10 per cent to 75 per cent of all pregnant women, even in those with normal hearts. This systolic murmur is most frequently heard over the pulmonary region, and the explanation for its presence depends upon a consideration of all the physiologic circulatory changes above enumerated. The distortion of the pulmonary conus, the venous congestion re-

sulting from elevation of the diaphragm, the slight anemia not uncommonly observed in pregnancy, the increased circulation time, etc., are adequate reasons for the appearance of such a murmur. Along the same line of reasoning one may readily explain the accentuation of the second pulmonic sound that is demonstrable in a very high percentage of normal pregnant women. A third physiologic physical sign, and sometimes the cause of distressing symptoms, is the occurrence of extra-systoles or premature beats. These are especially common in the later months of pregnancy and unless they are associated with definite signs of organic heart disease, have no clinical significance. The probable explanation of the extra-systoles is the distortion and rotation of the heart and the consequent production of foci of irritability outside the sino-auricular node.

After one has examined the heart of a pregnant woman and taken full account of all the physiologic phenomena occurring in every pregnancy, one is left with the difficult task of stating whether or not there is organic cardiac disease.

Proceeding now to a consideration of true heart disease in pregnancy, one is, of course, at the outset, interested in knowing the incidence and significance of heart disease among pregnant women. It is fair to state that at least 1 per cent of all pregnant women have some form of heart disease. As a cause of maternal death, cardiac disease follows in importance only puerperal infection and eclampsia. From the figures reported in the literature, maternal deaths attributable to heart disease would be between 5 and 8 per cent, or since some 18,000 women die yearly in the U S A during pregnancy or the puerperium, this would mean about 1,000 deaths annually from heart disease complicated by pregnancy. Heart disease with a superimposed pregnancy is a formidable complication.

During the childbearing age one has relatively few etiologic considerations in heart disease. The patient is too young for arteriosclerotic heart disease.

Hypertensive and syphilitic heart disease are not commonly encountered. A patient with subacute bacterial endocarditis rarely becomes pregnant. Various cardiac arrhythmias are observed during pregnancy, but their occurrence is so infrequent that space in this paper will not permit a discussion of their management. One is left then with rheumatic heart disease, congenital heart disease, and heart disease resulting from thyrotoxicosis. By far the most important of these is rheumatic heart disease, which accounts for 90 to 95 per cent of the lesions seen during pregnancy. The ensuing remarks are therefore most pertinent to the rheumatic form of cardiac disease. The valve lesion per se is of less importance than the functional ability of the myocardium, and no analysis of the relative frequency or performance of the heart with the various valve lesions will be undertaken in this paper.

The criteria used in establishing a diagnosis of heart disease in the nonpregnant are likewise applied to the pregnant woman. There are certain physical signs pathognomonic of organic heart disease, e g, diastolic murmurs, rough and transmitted systolic murmur, unmistakable cardiac enlargement, cardiac arrhythmia, other than extra-systoles, and unmistakable signs or history of cardiac failure. Moreover, a history of acute rheumatic fever or chorea or a history suspicious of congenital cardiac state are most useful.

When, on the basis of these criteria, one is able to establish a diagnosis of heart disease, one has fulfilled only part of his duty. The issue then resolves itself into estimating the ability of the heart to carry on during pregnancy and delivery, and a decision of the best way to manage the delivery. It is here that it becomes most essential to have the opinion both of the obstetrician and of the internist. Obviously the whole scheme of the medical man might be undone by the discovery later of a borderline or a contracted pelvis, from which one would naturally expect a lengthy and difficult labor. It

is at this stage that the debate *in situ* of the medical consultant and the obstetrician is most fruitful in outlining the best plan of treatment of the pregnant cardiac patient.

Everyone interested in the problem of heart disease and pregnancy has advanced beyond the point of diagnosis of the type of heart disease by making a classification of the functional ability of the diseased heart. Useful as these classifications may be, there is none flexible enough to fit every case. Every pregnant cardiac patient is an entity that must be considered as such, and each patient warrants a consideration of the social and economic factors of her case, as well as the pertinent medical and obstetrical data. Whether the cardiac patient can enjoy the luxury of a servant or whether she herself be the servant in the house is too obvious a point to require more than mere mention.

For purposes of discussion, however one does have to subdivide the cardiac cases in respect to their prognosis in pregnancy. The classification advanced by the New York Heart Association is very useful in keeping clearly in mind the functional state of the myocardium.

Into *Class I* are grouped the patients with organic heart disease able to carry on ordinary physical activity without discomfort. Many times patients in this group will give no history of rheumatic fever, and indeed the fact that they have a cardiac lesion may be brought to their attention for the first time with the physical examination during pregnancy. In other words this type of patient may have been so well compensated that she had no reason to consult a physician. For this patient the ordinary day's work has caused no symptoms, no undue fatigue, palpitation, dyspnea, and so on. On examination one finds the characteristic signs of well advanced mitral stenosis or combined mitral stenosis and aortic insufficiency, but rarely any real cardiac enlargement. Such a patient does not show the physical signs of congestive heart failure.

Patients in *Class I* rarely cause any concern during pregnancy. If the pelvic measurements are normal, a patient in *Class I* may be expected to go through the course of normal spontaneous delivery just as a noncardiac patient would do. These patients, whether primipara or multipara, should be admitted to the hospital several days or a week before the expected date of delivery. If the second stage of labor threatens to be lengthy, it is usually desirable to shorten it by the application of forceps.

The *Class II* cardiac group includes the patients with organic heart disease in whom the ordinary physical activities produce symptoms or discomfort. It is necessary to subdivide *Class II*. *Class II A* embraces the patients with mild symptoms and patients who are quite comfortable when their activity is slightly limited. They may have had one or more previous deliveries without cardiac embarrassment, yet on climbing stairs or doing some of the heavier forms of their housework, they experience shortness of breath. By increasing the amount of rest and restricting their physical activity patients in *Class II A* usually go safely through pregnancy and the puerperium. These patients also should be admitted to the hospital and their delivery governed exactly as the *Class I* patients.

Class II B includes patients with organic heart disease where their activity must be greatly limited and where cardiac failure is imminent. These patients frequently have failed in previous pregnancies. It is often a striking observation that the second pregnancy may have been a *Class II A* in the last two or three months before term and in the third pregnancy dyspnea on slight effort may appear as early as the fourth month. The prognosis in this group is serious. The *Class II B* patients should do no work.

The *Class II* patients confront the obstetrician and the internist with the very practical and important problem of deciding how many pregnancies the heart can stand before the cardiac grouping must be advanced. When one considers

that the Class II B patients are on the borderline of failure one has no alternative in forbidding the patient to have further pregnancies. How to prevent further pregnancies depends upon many factors, chiefly the intelligence of the patient in following contraceptive advice and the general philosophic outlook of the patient on childbearing. It is frequently desirable to sterilize such a patient and sterilization may be done at the time of delivery by cesarean section or during the puerperium. In patients above forty with organic heart disease sterilization by x-ray is frequently a satisfactory method. If the Class II B patient is a multipara with a normal pelvis it may be permissible to deliver her normally and sterilize her in the puerperium. On the other hand if the pelvis is of borderline dimensions, and the patient has had difficulty in previous deliveries, cesarean section may be the procedure of choice and section would carry with it the added feature of tubal sterilization. The Class II A patient offers more difficulty in the decision of the number of the children she should bear. If she desires more than one child she certainly should space her pregnancies with a period of at least two to three years between gestations. It is my personal opinion that the Class II A patients usually bear two children without particular difficulty but with subsequent pregnancies they advance to the Class II B or Class III. Therefore, I recommend that a patient in Class II A limit her pregnancies to two.

Class III patients are those with organic heart disease with frank cardiac failure, unable to carry on any physical activity. Their treatment is essentially the treatment of heart failure. The prognosis in this group is very grave and almost regardless of the course pursued obstetrically, the maternal mortality is approximately 50 per cent. It is an absolute rule that the heart failure be the prime consideration, and rest in bed, digitalis, and other well-known cardiac measures be instituted as early as possible. With this treatment, if there is

improvement, the patient should be kept in bed and digitalis continued through the pregnancy.

When to interrupt the pregnancy is one of the most difficult problems encountered in obstetrics. The pregnancy should not be interrupted until after cardiac therapy has been instituted and a sufficient period of time has elapsed for the patient to regain full or at least part compensation. If the patient is seen sufficiently early in pregnancy the interruption of the pregnancy may be carried out by cervical dilatation and curettage. Such interruption is highly advisable when heart failure has become manifest during the first three months of pregnancy. If, on the other hand, the pregnancy is of four or more months duration, when dilatation and curettage cannot be carried out, it may be wisest to allow the patient to continue with her pregnancy until the fetus is viable. The risk of operation would be essentially the same at either time. Frequently a cardiac patient in this class will fall into labor and abort spontaneously and Nature solves the problem. If, however, the pregnancy is allowed to continue and its duration becomes sufficient to insure a viable child, one is faced with the dilemma of a pelvic delivery or interruption by cesarean section.

There are many questions yet to be answered and there are many interesting points upon which there is not time for discussion. Before closing, I should like to mention one or two things about the general care of all pregnant cardiac patients regardless of whether they are Class I, II, or III. Every cardiac patient should be followed regularly throughout pregnancy and the puerperium. She should be examined at least every two weeks. She should have impressed upon her at every visit the importance of adequate rest and the avoidance of infection. I believe every cardiac patient should be delivered in a hospital and a medical man as well as an obstetrician should be responsible for her care. Ideally, admission to a hospital no less

than one week before the expected date of confinement is desirable. Under no circumstances should a patient with heart disease be submitted to the Trendelenburg position. If cesarean section is to be done, it is my opinion that open ether is the anesthesia of choice. If the heart failure is so severe that an inhalation anesthesia cannot be given, I would substitute morphine and local anesthesia.

The cardiac patient desirous of having more than one child will do best by spacing her pregnancies over a long period of time with at least two to two and a half years between each pregnancy.

In closing I should like again to emphasize the value of the joint opinion of the obstetrician and the internist in the care of the pregnant cardiac patient.

INCREASE IN SINUS INFECTION CURES PREDICTED

Because allergy has been found to be one of the primary causes of sinusitis (inflammation of a sinus) the number of cured cases will increase in the future. Herman Semenov, M.D., Los Angeles states in the *J.A.M.A.* for December 10.

His observations on 1 000 cases of sinusitis gave conclusive evidence of allergy in 17 per cent while in 35.4 per cent the history of allergy was not conclusive and in 47.6 per cent the inflammations were of nonallergic origin.

Other important causative agents of the ailment include colds, injuries and bacterial infections.

In sinusitis the mucous membranes of the sinuses become thickened and the mucus more sticky and elastic than it is normally, thus causing obstructions of the nasal passages. Successful treatment of chronic sinusitis obviously requires the removal of offending obstructions and elimination of the allergic agents. Simple drainage rarely provides satisfactory results in cases of pronounced thickening of the mucous membrane. Surgical measures generally are necessary.

In cases involving the chronic discharging of pus the failure of conservative drainage methods invariably indicates that there is a deep-seated infection of the glands and a degeneration of a cyst beneath the mucous membrane.

Surgery rarely is necessary in cases of sinusitis where there is no pus or thickening of the membranes. Nearly two-thirds of such cases are due to allergy, especially when both sinuses are involved.

Hypersensitive individuals are highly subject to inflammation and degenerative changes of the mucous membrane of all the facial sinuses. Thus the underlying allergic condition must first be treated before surgery is considered.

A NEW JOB FOR THE HUMBLE PIN

A simple and effective eye-dropper for oily preparations is described in the *British Medical Journal*. It is an ordinary domestic pin fixed in a suitable handle and the whole chromium plated. If the head only of the pin be dipped into the oil it will lift a globule of the right volume which by a touch on the mucosa of the lower lid is transferred to the eye. The dropper can be boiled. It avoids messiness and obviates too much being put into the eye by using a glass rod or dropper.

AESCULAPIUS TRUMPS

Oh spare me from the blatherings
Of those who while at gatherings
For bridge discuss their appendectomies
I'll rate as four star misuses,
Those sufferers with sinuses
Who jeer with scorn mere tonsillectomies
From those whose pet psychosis
Is their grandpappy's thrombosis
Or a recently discovered allergy
Who discuss their rheumatism
And their aunties' aneurysm,
May I forevermore delivered be!
To those whose whole exterior
Both frontal and posterior
Is scarred with stitches large and stitches small
May I say that operations
Forming inter-deal orations
Have most decidedly begun to pall.
Come let us in the future
Have our bridge without the suture
The scalpel, and the therapeutic ray
If you wish, before and after
Diagnose and heave the rafters
But while the game is on, SIT IN AND PLAY!
—Helen Hawthorne in *McLean's Magazine*

What to Expect from Treatment Criteria of Progress and Cure

The time is rapidly disappearing when it was necessary to issue a warning not to dismiss the patient on the day his last visible lesion was healed, or his first negative Wassermann was returned. Even so, the clearing up of external manifestations and the reduction of a positive serology to negative remain the principal criteria of a patient's progress under antisyphilitic treatment. We have merely arrived at a more critical interpretation of these signs of progress. Just how much to expect from a given treatment scheme applied to a particular patient is difficult to determine without some standards of comparison. I am strongly inclined to believe, in the light of comparative studies carried out in the Vanderbilt Clinic and elsewhere, that the widespread use of substitutes for arsphenamine, the more or less haphazard methods of planning treatment, or, even more, the lack of planning, have tended to obscure the standard of what one has a right to expect from the treatment of syphilis particularly in its early stages. The physician who is satisfied with the results he has obtained with neoarsphenamine is likely to be unaware of the fact that he might in all probability have secured the same results in little more than half the time with another arsphenamine preparation, and that many a 'resistant' case is only a poorly treated one. The tendency to keep a patient under treatment for periods of two, three, five years, or even longer, can be traced in large part to the uncertainties inherent in treating with arsphenamine substitutes, and to having no definite plan.

The Clinical Response—A chancre, if of fairly recent origin and uncomplicated by some other infection, will generally heal after a very few injections of arsphenamine, in a young and otherwise healthy subject. Mucous patches and condylomata disappear with astonishing rapidity, while the early generalized macular eruption will usually clear within two or three days after one injection, and almost always after two injections of

arsphenamine. The late secondary eruption is generally more resistant. Gummata respond quickly to arsphenamine, often melting away completely after a few injections, the ulcerative processes require more time.

Marked subjective improvement is common within twenty-four to forty-eight hours after the first arsphenamine injection, and continued treatment is nearly always paralleled by a gain in weight and improvement in the general physical condition. This improvement will be more substantial if the specific treatment has been buttressed by a diet nourishing and rich in vitamins, which is especially necessary to offset dietary restrictions on treatment days, and by additional rest and moderate exercise.

The following results obtained in the treatment of fifty-eight patients with primary syphilis, under clinic conditions, show the relative efficacy of three different arsphenamine preparations.

| | OLD ARSPHENAMINE 20 CASES | SILVER ARSPHENAMINE 25 CASES | NEO- ARSPHENAMINE 13 CASES |
|--|---------------------------------|------------------------------------|----------------------------------|
| Average time and injections required for complete resolution of chancre | 12 5 days 3 1 inj. | 18 4 days 6 4 inj. | 21 3 days 4 8 inj. |

The Serologic Response Tests of Blood and Spinal Fluid—During treatment of early syphilis we recommend that a blood Wassermann be taken once a week, before the injection, and never less often than once a month. In early syphilis a positive blood Wassermann may be expected to become negative by the end of the first course or during the early part of the second course of arsphenamine, if it does not, at least one full course of arsphenamine and one full course of a heavy metal should be given after the first negative. The fact that in some early cases the Wassermann will become negative after the first few injections should not lead one to shorten the prescribed course of treatment. Conversely, the temporary positive which occasionally supervenes in the seronegative primary stage after treatment is begun

should not be construed as a relapse, it indicates that the patient's blood was on the verge of a positive reaction when treatment was initiated, and that the first arsphenamine injection acted as a provocative.

It should be understood that for patients with early syphilis the minimum standard treatment outlined should be pursued regardless of serologic reactions during the first year, but upon these serologic reactions depends to a large extent the disposal of the case at the end of the year. If the spinal fluid should be found positive at any time during the first six months of the syphilitic infection, treated or untreated, but no symptoms of neurosyphilis are in evidence, it is best to carry out the regular treatment for early syphilis to the end of the year and then re-check. For the occurrence of a positive blood or spinal fluid beyond the first year of treatment, see under the topics "Wassermann-Resistant and Relapsing Cases" and "Neurosyphilis."

During the treatment of late syphilis a Wassermann test should be done once a month, and never at longer intervals than three or four months. Barring some definite indication to the contrary, treatment for tertiary and latent cases should be pursued for at least one year, as outlined, regardless of serologic response. A positive Wassermann persisting beyond this time calls for special consideration, as explained in subsequent topics.

Criteria of Cure—We are now to suppose that the patient admitted with early syphilis has pursued the standard course of treatment for one year, as outlined. To be eligible for discharge, he must have fulfilled the following requirements:

1. He must have completed one year (never less than eleven months) of regular and continuous treatment according to plan.

2. He must have been free from both external and serologic evidences of syphilis for not less than six months, and he must have received not less than one complete course of arsphenamine and one

complete course of bismuth or mercury after the first negative Wassermann.

3. The spinal-fluid test (Wassermann, colloidal gold and cell count) must be negative at the end of the first year. A negative spinal fluid at the end of the first course of treatment serves as an additional guarantee against neurosyphilis.

4. A complete physical and neurologic examination, supplemented by roentgenograms of heart and aorta, and by electro-cardiogram, must disclose no evidence of syphilis at the completion of the prescribed treatment.

The Follow-Up—When a patient has completed the first year of standard treatment and has fulfilled the requirements for discharge, he should be told to return for a blood test at intervals of three months during the next year. If these trimestrial tests are consistently negative, he should return during the next two or three years at six-month intervals and thereafter at yearly intervals.

A complete physical examination, including tests of blood and urine, should be given not less than once a year, and preferably every six months, after the patient has been discharged from treatment. Since the periodic physical examination is generally recommended, even for persons without a history of syphilis, it is obviously all the more important for those who do have such a history. The patient can easily arrange for a blood Wassermann to be added to the usual annual or semiannual physical examination, if this is not already a part of the routine procedure.

Permission to Marry—A patient who has completed the required treatment and has remained free from symptoms of any kind for one year after discharge may be permitted to marry, upon the understanding that he adhere scrupulously to the follow-up policy outlined above.

In most of the above discussion we have assumed that the patient pursued the prescribed treatment for one year, and that his response was satisfactory enough to make him eligible for discharge on probation at the end of the year. If the

patient has not responded favorably to regular and continuous treatment as outlined, or if he has been irregular in attendance, or unable to tolerate average doses of the preferred drugs, treatment must then be continued into the second year, with modifications to suit the individual case.

Wassermann Resistant and Relapsing Cases—A small percentage of early cases and a larger percentage of tertiary and latent cases, including the congenital ones, will fail to show a serologic response to the routine forms of treatment, or will fluctuate unaccountably between positive and negative. In such cases the spinal fluid test, advocated as a routine measure at the end of the first year of treatment, is likely to be particularly revealing. If the spinal fluid is positive, the patient should be treated for neurosyphilis, even though no clinical symptoms are as yet in evidence. If the spinal fluid is negative and the patient symptom free, one may properly suspect drug fastness, and a change from one arsphenamine preparation to another—also a change from mercury to bismuth or vice versa—will often bring results. In congenital syphilis and in some forms of neurosyphilis which have been treated by the usual methods over long periods of time without a negative Wassermann having been obtained, it is permissible to try malaria, typhoid vaccine, or fever box therapy.

When a patient previously discharged and under observation shows a single positive Wassermann after a series of negatives, it is best to wait a few weeks and then repeat the test, sending samples to two or more laboratories for comparison. This precaution is all the more necessary if the Wassermann is only partially positive. Meanwhile a careful search should be made for any clinical signs which may possibly have been overlooked in the routine physical examination. If any such signs are detected, or if the patient presents any lesion which might be thought to be syphilitic, or if several Wassermann tests, preferably made by different laboratories, have in the interim been declared positive a pro-

vocative injection of arsphenamine is in order. This treatment should be followed by a series of Wassermann tests at intervals of forty-eight hours, three days, five days, seven days, ten days, and two weeks. If a strongly positive Wassermann develops under these conditions, it may be construed as an indication for specific treatment. Without these safeguards, I should consider it unjustifiable to resume treatment on the evidence of a single positive Wassermann, after a patient has fulfilled the prescribed requirements for a cure.

Cure and Reinfection—It should not be forgotten that, contrary to what happens in most other infectious diseases, immunity in syphilis, so far as is known, lasts only as long as the disease. Once he is cured the patient may acquire a fresh syphilitic infection, in which case he should be treated as for the original infection. Many of the so-called "reinfections" reported in the literature, and adduced as proof of cure, are in all probability relapses in patients inadequately treated. Not until a patient has fulfilled strictly the requirements outlined above, and has remained clinically and serologically negative over a period of years, is one entitled to speak of a "cure."

Modifications of Routine Treatment for Special Types of Cases

Aortitis and Hypertension—The usual treatment for late syphilis may be given if special pains are taken to avoid reactions.

Aneurysm, Myocarditis, and Cardiovalvular Disease—These diseases call for rest in bed and sharp limitation of physical activity. Only patients with special types of aneurysm should receive arsphenamine, and then only in small doses, not oftener than once a week, and preferably while resting in bed. In general, for patients with aneurysm, myocarditis, or cardiovalvular disease it is best to use bismuth and mercury in alternating courses, along with potassium iodide.

WARNING! Antisyphilitic treatment of all kinds should be avoided in cardiac cases with decompensation.

Nephritis—Nephritis responds best to arsphenamine alone. The dose and intervals should be modified according to the requirements of the particular case, though moderate doses at weekly intervals are usually found to suffice. Syphilitic nephritis clears up with surprising rapidity under antisyphilitic treatment.

Hepatitis—Treat preferably with heavy metals and the iodides. It is better not to give arsphenamine to patients with hepatitis, especially in the first few months of treatment, and then only after careful tests have been made of the functional capacity of the liver. These tests should include the bile index, the Van den Bergh test, and tests for blood arsenic, and should be repeated at least every two weeks, and preferably every week.

Tuberculosis and Syphilis—No patient with actively progressing tuberculosis should receive antisyphilitic treatment unless he has infectious syphilitic lesions, in which case just enough treatment should be given to clear up the open lesions, usually a very few injections of arsphenamine will suffice for this. Caution should be observed in the treatment of syphilitic patients with arrested tuberculosis. Small doses of arsphenamine should be given at weekly intervals, not more than six or eight injections in a course, followed by a course of bismuth. Mercury and iodides should be avoided. Special pains should be taken to prevent reactions of all kinds. Any untoward symptoms or loss of weight should be taken as an indication to stop treatment. When the usual treatment for tuberculosis does not bring the expected results, especially in cases in which the diagnosis is open to question, and the patient has a history of syphilis or a positive serology, one is justified in treating him for syphilis, observing the precautions outlined above. Some of the cases originally diagnosed as tuberculosis are in all probability syphilis of the lung. These show striking improvement under specific therapy.

Anemias respond well to small to moderate doses of arsphenamine given at

five- to seven-day intervals. Courses of arsphenamine should be followed by bismuth and potassium iodide. Mercury is usually contraindicated. Special care should be taken to build up the blood by means of a diet rich in vitamins, plus iron and liver extract.

Special Cases for Malaria Treatment—In addition to its use in neurosyphilis, malaria may be used to advantage in the following types of cases:

a Wassermann-resistant cases, all forms, including congenital.

b Interstitial keratitis in the acute stage give regular treatment for early syphilis, and then follow with malaria.

c Early syphilis in cases in which the time element is important, as in transients in city institutions who cannot be kept long enough to complete the usual routine treatment, malaria has the advantage of keeping the patient hospitalized long enough so that at least one and usually two complete courses of arsphenamine can be given.

Kyrle of Vienna, treating patients with early syphilis, found that by using arsphenamine, supplemented by malaria, he was able to achieve a satisfactory clinical cure and to prevent neurosyphilis.

Outline of Treatment for Neurosyphilis

Of all the forms of syphilis, none is so insidious in onset, so deceptive in manifestations—or lack of them—and so unpredictable in its course, as that involving the nervous system. By the time clinical symptoms are fully apparent to the diagnostician, the disease has usually progressed so far that the most to be hoped for is a temporary arrest of the process and relief from the more troublesome of the symptoms. It is therefore doubly important to detect, if possible, the first advance of the parasite upon the nervous system, which may occur even before the secondary skin eruption has appeared.

Early Neurosyphilis—A Asymptomatic—The first evidence of involvement of the nervous system is to be found in the altered reaction of the spinal fluid, a marked increase in the cell count and

globulin, and the more or less strongly positive Wassermann and colloidal tests (gold or mastic) For this reason the ideal procedure would be to make a routine test of the spinal fluid of every patient admitted for the treatment of syphilis, of whatever stage Practically, however, this early preclinical neurosyphilis is almost certain to involute by the time the patient has completed the first course of regular treatment for early syphilis A test of the spinal fluid performed at this time will serve to confirm this in the great majority of instances, while in the occasional case with positive findings the physician will be on his guard throughout the subsequent courses In any case, then, in which the blood and spinal fluid are both found to be strongly positive within the first six months of a syphilitic infection, treated or untreated, and there are no clinical manifestations of neurosyphilis, one may safely proceed with the usual treatment for early syphilis If at the end of the first year of regular treatment for early syphilis, a patient shows a positive blood and a positive spinal fluid, even though no symptoms of neurosyphilis are in evidence, a more radical form of treatment is indicated, as for late neurosyphilis

B Meningeal—In early neurosyphilis of the meningitic type which has developed within the first two years of infection but which has as yet shown no evidence of degenerative processes in brain or cord, intraspinal therapy should be given. Sometimes one or two treatments are sufficient to bring about a reversal of the positive spinal fluid and a disappearance of symptoms One may then proceed with the standard treatment.

Late Neurosyphilis—The majority of cases of advanced neurosyphilis will be found either in persons who have never received any antisymphilitic treatment or in those who have been inadequately treated at some more or less remote period. In all cases of late neurosyphilis except those in which the patient has received fairly recent treatment—that is, within the past two years—it is safer to begin with the heavy metals and iodides,

pursuing the standard treatment plan used in tertiary syphilis for several months, and examining the spinal fluid at least every four to six weeks If there is no appreciable change in the serologic or clinical findings after four to six months of the standard treatment for tertiary syphilis, it is then incumbent upon the physician to make a choice from among the various types of treatment specially adapted to neurosyphilis, namely, intraspinal therapy, malaria, or other forms of fever therapy, and tryparsamide, supplemented by the heavy metals and iodides From the following outline it can be seen which of the special types of treatment are best suited to each of the different forms of advanced neurosyphilis

A Malaria is indicated in

1 All cases of general paralysis and preparetic states.

2 All cases of neurosyphilis in congenital syphilitics.

Malaria is contraindicated in elderly patients and those with cardiac disease, nephritis, or other serious constitutional disability

B Intraspinal therapy is indicated in

1 All tabetic types in patients suffering from shooting pains or gastric crises, intraspinal therapy not only brings down a positive spinal fluid but frequently gives marked relief from symptoms

2 Optic atrophy intraspinal therapy will often arrest the process and maintain vision stationary, if treatment is persisted in long enough, the spinal fluid may become negative.

3 Elderly persons with active neurosyphilis, and patients with cardiac disease, nephritis, or other serious constitutional disability in whom malaria would be dangerous

4 Patients with active neurosyphilis who have already had malaria treatment and who do not react to subsequent inoculations

C Tryparsamide is indicated as follows

1 One course before beginning malaria treatment, and another afterward,

Figure 1 The Cannon Needle for Lumbar Puncture long-sleeved stylet partly withdrawn, uncovering inner sheath of hub, which is protected from contamination when stylet is in place

alternating courses of tryparsamide with heavy metals and the iodides

2 In rare cases of tabes, where the patient is below par physically and pain persists in spite of intraspinal therapy

D Tryparsamide is contraindicated in

1 Optic atrophy and cranial nerve deafness

2 Tabetics with marked ataxia and those with bladder and rectal symptoms, tryparsamide sometimes increases these symptoms

3 Early syphilis. Tryparsamide is not a treponemicidal drug, and should never be used in routine treatment of early syphilis, but in neurosyphilis it often brings about a gain in weight and improvement in the patient's general condition

WARNING! Tryparsamide often causes optic neuritis, hence the eyes should be examined before and at intervals during courses of treatment. The drug should be discontinued at once if the patient becomes aware of any visual disturbances, however slight. The first abnormality detected by the ophthalmologist is usually a contraction of the visual fields, but this is frequently preceded by subjective symptoms. The patient, if questioned, will complain of seeing black and yellow dots or streaks, or of letters running together, while as yet no objective changes can be detected. Stopping

the drug at this point reduces the danger to a minimum

A positive spinal fluid is always an indication for treatment, even when no symptoms are in evidence. If the patient remains untreated it is only a matter of time before symptoms will appear, but treatment, in the majority of cases, will serve to forestall the appearance of symptoms. The age of the patient, his

Figure 2 The Cannon Needle for Lumbar Puncture long-sleeved stylet locked into position, ready for puncture

earning capacity and life expectancy, number of dependents, etc., should be taken into consideration before the more radical forms of treatment for neurosyphilis, particularly fever therapy, are undertaken. If the patient is a fairly vigorous person in the forties or early fifties, active treatment for neurosyphilis may add many years to his business, family, and social life. But if he is well on into the sixties or beyond, is not very vigorous, and has no immediate dependents, it is usually best to limit oneself to the milder forms of treatment.

Technic of Lumbar Puncture

The essentials of a successful lumbar puncture may be reduced to the following: (1) proper selection and care of instruments, (2) preparation of patient, (3) determination of puncture site, and (4) technic of puncture.

Selection and Care of Instruments—Strict asepsis is imperative in any opera-

tion involving the spinal canal. At the same time, the formidable array of equipment pictured in most textbooks is likely to deter the practitioner from making a spinal test or from instituting treatment which is of vital importance to his patient. In performing a spinal puncture, the chief possibility of contamination lies in the needle, which must be handled directly by the operator. Some of the escaping fluid will dribble over the edge of the hub previously handled. This is especially dangerous when fluid is being withdrawn for treatment, for a few drops of this contaminated fluid may easily be washed back into the spinal canal and cause infection.

To obviate this danger a special needle was devised. This needle has a cylindrical hub made in concentric parts, chief of which are a long smooth inner sheath continuous with the hollow shaft of the needle, and a short corrugated outer sheath or hilt, by which the needle is grasped when the stylet is not in place. The stylet is capped with a long cylindrical sleeve which fits down over and completely covers, without touching, the inner sheath of the hub, being locked to the outer sheath by a notch and pin device. In performing a spinal puncture with this needle, the operator's fingers do not come in contact either with the shaft, or with that inner part of the hub which receives the spinal fluid. The hub is somewhat heavier than that of the ordinary needle, and thus helps to direct the course of the needle in its passage into the canal. The additional protection provided by this comparatively simple arrangement reduces the risk of infection to a minimum and makes it possible to perform the operation, for either diagnostic or therapeutic purposes, in a private office, with a minimum of equipment.*

In the usual spinal puncture for withdrawal of fluid only, a 21 gage needle is used, for intraspinal therapy a slightly larger bore (19 or 20-gage) is preferable.

* The Cannon needle for lumbar puncture is manufactured by Becton Dickinson and Co. Rutherford, N. J.

Figure 3. Determination of site for lumbar puncture. If tip of third or index finger is placed on superior iliac crest and thumb is extended at right angles, thumbnail will be in position to mark third or fourth lumbar interspace (either may be used). For details see text page 202.

Each needle must be sharpened to a very fine point, bevel edge and point must be absolutely smooth and free from rust. Needles should be thoroughly washed with soap and water, then allowed to stand in olive oil, the oil removed with ether (alcohol will corrode), and the needles sterilized with dry heat. For sterilizing, the needle is placed in a test tube with cotton at the closed end, and the tube is then plugged with cotton or gauze. It should be left in the dry sterilizer for two and a half to three hours at a constant temperature of 212 F.

Preparation of Patient—The patient should lie on his side, with knees flexed over the abdomen, head bent down as close to the knees as possible and resting comfortably on small flat pillow. If the patient is nervous, his hands may be

Figure 4 Technic of lumbar puncture showing patient and operator in position. The patient lies on her side, with knees flexed over abdomen, head bent down as close to knees as possible, and upper shoulder inclined slightly forward, lumbar region is at edge of bed, in a vertical plane. Note comfortable relaxed position of operator, who sits well away from patient, so that when the arm is extended, the forearm is on a line with the site selected for puncture.

locked over his knees. When the patient is in position, the lumbar region should be at the edge of the bed, in a vertical plane. To avoid twisting of the spinal column incline the upper shoulder slightly forward. It is better for the physician or nurse to make minor adjustments, encouraging the patient to relax.

Determination of Puncture Site—If the tip of the third or index finger is placed on the superior iliac crest and the thumb is extended at right angles, the thumb-nail will be in position to make a horizontal mark in the third or fourth lumbar interspace (either may be used). Now release the index finger and allow it to

slip forward over the fourth or fifth vertebral process (whichever forms the lower boundary of the interspace to be punctured). Just proximal to the bony ridge, make a vertical mark with finger nail. The intersection of the two nail marks indicates the site to be punctured. This, the distal portion of the groove or interspace, is preferable to the exact center, in case a sudden straightening-out movement on the part of the patient should close the groove.

Technic of Puncture—As a routine measure the operator washes his hands thoroughly with soap and water, followed by 70 per cent alcohol. The puncture site should be thoroughly wiped off with iodine, followed by 70 per cent alcohol, and then anesthetized with a 2 per cent solution of procaine hydrochloride, injected through a small hypodermic needle. Infiltration of the skin will be marked by the appearance of a pea-sized wheal. Without withdrawing the needle, the syringe should be elevated and the remainder of the procaine hydrochloride injected slowly, right up to the hub of the needle. Besides anesthetizing the skin and underlying tissues, this will serve as a guide in performing the lumbar puncture.

The operator now adjusts his position by sitting well away from the patient—almost at arm's length—so that when the arm is extended, the forearm is on a line with the site selected for puncture. The needle is grasped by the exposed portion of the hub, and the stylet, after being moved up and down to make sure that the lumen is patent, is locked into position. The hub (now protected by the long sleeve of the stylet as previously described) is taken between thumb and index finger, and allowed to rest on the middle finger. The operator, thoroughly relaxed, flexes the wrist in order to get a straight alignment with the mark, making sure that the point of the needle is directed straight in and slightly cephalad. The patient is then asked to take a deep breath, and at the height of inhalation, the operator, by a quick wrist motion, thrusts the needle in $1\frac{3}{4}$ to 2 inches. The depth will de-

pend upon the amount of adipose tissue, on very obese patients it may be necessary to thrust needle in five or occasionally even six inches. The sudden feel of lessened resistance, sometimes audible as a slight snap, indicates that the point has penetrated the dura and is in the canal. The operator should at once remove the stylet and allow a few drops of fluid to escape. As soon as it is apparent that the fluid is clear, 5 to 8 cc is collected in one test tube for the Wassermann and colloidal gold tests, and 2 cc in another tube for the cell count and globulin determination.

The patient should lie face downward for at least half an hour, preferably for one or two hours afterward.

The Management of Difficulties—If the preliminary instructions for placing the patient and selecting the site for puncture have been carefully followed, any failure that occurs can usually be attributed to faulty posture on the part of the operator. A cramped position, with elbow bent and wrist tense, and introduction of the needle by a slow boring motion, makes the operation needlessly difficult. It is of the utmost importance that the operator be seated in a comfortable position, with wrist and forearm completely relaxed. If the wrist is tense, it should be shaken out and flexed back and forth several times to get the alignment before the needle is thrust in. The needle should be allowed to take the course of least resistance.

When the operator estimates that he has gone the proper distance, but is uncertain whether the canal has been entered, he should remove the stylet, taking care not to allow it to touch anything. If no fluid appears, he should reinsert the stylet and advance $\frac{1}{8}$ to $\frac{1}{4}$ inch farther, repeating the process until he either obtains fluid or strikes bone. If bone is struck the needle should be withdrawn almost to skin level and redirected laterally up or down. If blood is obtained, the needle should be rotated half way around. If the fluid does not become clear after a few drops have been allowed to run out, it should be with-

drawn completely and a puncture made in the adjoining interspace.

Technic of Intraspinal Treatment

Preparation of Serum—The patient is given the usual dose of arsphenamine. One-half hour later, under sterile precautions, approximately 50 cc. of blood is withdrawn in a small necked centrifuge tube, using the McRae needle or a syringe. A sterile cork is inserted, covered with sterile gauze, and fastened on with a rubber band. The tube of blood is kept in the icebox overnight. The blood is then centrifuged for thirty minutes to separate clot from serum. The serum is then pipetted off into another tube and centrifuged in order to remove all blood cells. It is pipetted off a second time into another sterile tube. The amount at this point will average about 20 to 25 cc. This is now placed in a water bath and maintained at a temperature of 56 to 57½ C. for thirty minutes in order to destroy complement (serum is about twenty times more treponemicidal when complement is destroyed). The serum is now ready for injection at body temperature.

Technic of Treatment—A spinal puncture is done in the usual way. Five to 8 cc. of spinal fluid is collected in one test tube for the Wassermann and colloidal gold tests, and in another, 2 cc for cell count and globulin determination. To the spinal needle a Snyder gravity tube is now attached (the barrel of a 50 cc. syringe or a huret may also be used) by means of a section of rubber tubing 18 to 24 inches long, with male adapter at end. By lowering the Snyder tube, 30 to 40 cc. of spinal fluid is allowed to gravitate into it. It will often happen that a patient will complain of severe headache after about 30 cc. of fluid has been withdrawn. In this case stop at once, but if the patient does not have too severe a headache, the tube may be allowed to fill to within $\frac{1}{4}$ inch from the top. The Snyder tube is now elevated and as the spinal fluid begins to gravitate slowly back into the canal, the serum is added drop by drop. This insures a thorough mixture outside

Figure 5 Close-up of operator performing lumbar puncture. Hub of needle is grasped between thumb and index finger and allowed to rest on middle finger, point of needle is directed straight in and slightly cephalad. Needle is thrust in $1\frac{1}{4}$ -2 in. on patient of average build.

the body, and in such a way that the first of the fluid to be returned contains the lowest concentration of the medicated (and potentially irritating) serum, the concentration increasing as the tube is emptied. When the tube is empty, milk down the remaining fluid through the rubber tubing and needle. If possible, about 20 cc. more of the mixture is introduced than the amount of fluid withdrawn, in order to produce an increase in intraspinal pressure. Withdraw the needle in usual way and put on dressing. The patient may go home in twenty-four hours.

Courses of eight to ten injections at two-week intervals are given in cases of cerebrospinal syphilis and in early tabes. There should be an interval of one and

one-half to three months between courses. In advanced tabes with marked functional disorders, such as pronounced ataxia, incontinence of bladder, anesthetics, treatments are spaced at longer intervals (three to six weeks).

Prevention of Reactions to Intraspinal Treatment

Care of Patient—After the injection, have the patient lie face downward.

Figure 6 Lumbar puncture completed, syringe withdrawn and fluid being collected for test.

at least one-half hour. If a reaction occurs after the first injection the patient is usually given aspirin (10 grains), phenacetin (10 grains) and codeine (grain) one-half to three-quarters of an hour before the next anticipated reaction. This will either prevent or greatly modify attacks of pain. Avoid all hypodermic medication unless absolutely necessary.

Timing of Blood Withdrawal—In

eral, the incidence of reactions after intraspinal treatment is proportional to the dose of arsphenamine which the patient has received intravenously, and to the interval which is allowed to elapse before the blood is withdrawn. Serum from blood withdrawn within ten to fifteen minutes after the injection of a full sized dose of arsphenamine is highly toxic, and almost certain to cause a reaction. Unfortunately, as the dose is decreased and the interval lengthened, the serum tends to lose not only its toxicity but also its therapeutic properties as well. I have found thirty minutes after the arsphenamine injection to be the best average time for the withdrawal of blood, as advocated in the Swift-Ellis procedure. When there is marked involvement of the posterior nerve roots, as evidenced by ataxia, anesthetics, and irritability of the bladder and rectum, it is necessary to compromise by giving relatively smaller doses of arsphenamine and delaying withdrawal of blood until one hour afterward. Various studies indicate that the beneficial effect is due, not to the direct action of the arsphenamine itself, but to antibodies produced in the serum, probably by the arsphenamine or the syphilitic infection, or both.

Therapeutic Malaria

Malarial treatment should not be attempted unless the patient can be hospitalized under close medical supervision. Under no circumstances should it be instituted without establishing in advance that the patient's general physical condition justifies the risk involved (see "Contraindications to Malaria" under "Outline of Treatment for Neurosyphilis").

Technic of Inoculation—Blood should be taken from a patient infected with *Plasmodium vivax*, the parasite of benign tertian malaria. Suitable patients can be found in most neurologic and psychiatric institutions. Patients infected with tropical malaria should not be used. Withdraw 2 cc. of blood from the malaria patient, preferably an hour or so after the chill, at the height of the fever. One or two cc (never more than two) of the

whole blood is given to the syphilitic patient as soon afterward as possible. If it is not to be used immediately, the blood must be citrated by adding to it an equal quantity of a 0.5 per cent solution of sodium citrate. When blood is transported from the donor to the recipient, the tube should be carried in the inside vest-pocket to keep it warm. It may be kept for a day or two in an incubator. In order to be sure of a "take," in addition to injecting 1 or 2 cc intravenously, one may inject 1 cc. of the malarial blood intramuscularly in the same patient. Typing of blood is not necessary when such small quantities are injected.

Management of the Patient—The first chills and fever usually occur five to seven days after an intravenous injection, and ten to fourteen days after an intramuscular injection. If the patient does not develop symptoms of malaria within three or four days after the expected time, the attack may be induced by intramuscular injections of milk, colloidal manganese, or typhoid vaccine. The paroxysms of chill and fever last for several hours, and may occur daily or every three or four days. The temperature should be taken every few hours between paroxysms, and every half hour during the fever; it should not be allowed to exceed 106° F. The attack may be broken off at any time, or reduced in severity, by the administration of quinine—10 grains every four hours for three to five days. During the course of the malaria a careful record should be kept of temperature, pulse, and respiration, and of fluid intake and output. Frequent red blood counts and urinalyses should be made, and the blood pressure taken daily, both during and between paroxysms. The heart and spleen should also be examined frequently, and from time to time the blood should be examined for malaria parasites. During the periods of normal temperature it is advisable to give a nutritious diet, because on the days of chill and fever there is usually a complete loss of appetite. After the termination of the course a nutritious diet, cod liver oil, and iron are

in temperature will gradually limit them selves to 100 or 101 F for the remaining attacks. In still other cases the attacks throughout do not exceed 101 F. I have noted just as much clinical and serologic improvement in those patients who run a mild febrile course as in those who run a high temperature. Hence it seems questionable what influence the fever itself actually has on the course of the disease. For all practical purposes, if the patient develops malaria with parasites demonstrable in his blood, and runs eight to ten successive paroxysms of fever with or without chills, one will have met the requirements.

Failure of Inoculation—A certain num

ber of patients, including not only those who have had malaria before but also some with no previous history of malaria, will be refractory to malaria. If either donor or recipient has recently been treated with quinine, inoculation may fail. In such cases one must resort to typhoid intravenously, fever box, or intraspinal therapy.

The cost of malarial therapy may be cut down by allowing the patient to delay entering the hospital until three or four days after inoculation.

The Outline of Treatment for Syphilis which has been published serially is concluded in this issue

HOW ILLINOIS DOES IT

The Illinois State Department of Public Health has announced that sulfanilamide is available free on requests of physicians for the treatment of patients suffering from gonorrhea. The only requirement is that the request be accompanied by a report of the cases for which the drug is desired. Cases may be reported by

either name or code number. Any physician in Illinois may obtain sulfanilamide sufficient to treat any and all gonorrhea patients under his care who in the physician's judgment will be benefited thereby.

The drug is distributed in vials of 100 tablets of 5 grains each.

Special Article

"QUO VADIS?"

Address by LEO F. SIMPSON, M.D., on the occasion of the Dedicatory Dinner, Rochester Academy of Medicine, held at the Oak Hill Country Club, January 12, 1939

AS YOU possibly suspect, we are here tonight to participate in the inaugural ceremonies of our new home, and to again congratulate Dr. Albert D. Kaiser. The members of the Rochester Academy of Medicine, together with all other physicians in Monroe County, must indeed have feelings both of thanksgiving and of responsibility.

Our heartfelt gratitude goes out to the daughters of Mr. and Mrs. Edmund Lyon who have, by their generosity, carried on into the future years, the charity, the thoughtfulness for the unfortunate, and the high sense of civic responsibility, so nobly exemplified by their parents during their stay on earth.

We are also deeply indebted to those public-spirited citizens of Rochester who contributed two-thirds of our endowment fund of \$150,000. This was indeed an intelligent vote of confidence.

Such generosity and such confidence carry with them the implication of a faith and a trust that must be lived up to to the limit of our capacity. Our service to the individual, and to the community, must be revitalized by such a manifestation of confidence, else their gifts become but funny shapes of brick and mortar—nothing more. We have little doubt that with these increased facilities for its library, for its meetings, for its various groups of specialized study, that the Rochester Academy of Medicine, in the years to come, will amply repay this community in ever greater dividends of health, and relief from suffering.

It is not to the generous people of whom I have spoken that medicine must make a new appeal. They have a sense of real values. Their emotional tone is of the highest quality and is guided by

keen intellect. They know what organized medicine has done for the community, and they would have it live and carry on.

But it is a coincidence that the Rochester Academy of Medicine should have come into possession of the home, now being dedicated, at a time when the results of the efforts of a self-governing profession in the care of the sick of this country, are being called into question.

Medicine is now on trial before the bar of public opinion. We seem at present to be a profession peevishly scolded, criticized as reactionary, suspected of keeping back invaluable secrets, callous to the poor and the underprivileged—a monopoly in restraint of trade.

The members of the Academy of Medicine have risen to their present prominence in this community because in spite of little jealousies among ourselves, each man put forth his best as an individual, and hoped always to be rewarded by individual recognition. As a result, people of all classes have reaped the reward of our individual striving. There is no other force on earth that could call forth such efforts.

We know that as a result of his education and training, the doctor is psychologically conditioned to heal. His greatest satisfaction lies first and foremost in healing. The will to heal becomes part of him. On the other hand, there is developed in the patient who has freedom, individual responsibility and rewards, the will to get well. Bring these forces together—the will to heal and the will to get well—and you have the power that has made American medicine great. Take away, under bureaucratic supervision and interference, the will to heal, and take away, with liberty, the will to get well and

replace it with the will to malingering—and the result is government medicine

In the study of disease and in the medical care of the individual, whether preventive, curative, or palliative of incurable disease, medicine has been in part socialized for a long time—using the word to imply the use of tax funds to pay doctors for the work they do. We agree that much of it, especially in public health work, in the care of the insane, in tuberculosis, etc., is justifiable. But when the state endeavors to extend its medical activities to accompany the doctor across the threshold of the sick room and place the government's hand on the patient's pulse, and demand a record in triplicate of his ills and possible sins—then organized medicine says "no." Then it is time for medicine to become truly militant.

Let the business man know in no uncertain terms that if the sacred private practice of medicine be socialized, then his taxes are only beginning, and that his business structure itself is next because he is accused also of failure in caring for the "submerged third." Let the press as it recognizes the ultimate dangers to its own freedom, inherent in this manifestation of public policy, come to our assistance wholeheartedly and without hesitation. Let the fathers and mothers whom you have served so well be roused from their apathy, and straighten out their sense of relative values. Let the lawyers join in, for if there are to be no individual rights, what need will there be for lawyers? And what say the clergy?

Go to the people and he not afraid. Do not, however, assume that the people know what you have done, and will never desert you. Let the medical society, if it has to, peddle from door to door the priceless things that the private practice of medicine has given them in the past. The people themselves are not asking for a change. The simple fact is that the results obtained in America under this system far exceed, by whatever standards measured, those secured in any other country whose methods we are now asked to copy.

Why is medicine now being used as a

'whipping boy?' Is it really at fault? Or does the fault lie deeper? Let us make a possible diagnosis, and suggest treatment.

We are living in an age of tremendous unrest and change. Formidable forces are at work with devastating rapidity. New instrumentalities of science and invention are transforming our lives. Our efforts to keep our place in the modern and bewildering parade have left too large a portion of our people confused, frustrated, insolvent, and, I fear, rebellious. Government has attempted to relieve and to stem this flood of dissatisfaction with sandbags of money. If the flood rises, other sandbags, made of the practice of medicine will be thrown in, and others can be made.

All is changing but man himself. In the mass he is essentially as he was centuries ago, and as one index of his struggle, we have the record of over 55 per cent of our hospital beds in the United States occupied by the insane. This is indeed a choice indictment. If this gives any indication of our future trend, we must quickly decide whether the happiness of man, or his prosperity, should be our goal.

The problem, as I have said, is man himself—the comparatively unchanging, limited human being. The doctors' problem is how to keep him sane and contented in the future. To center on material prosperity alone, and to assume offhand, that the majority of men have the power of unlimited rational adjustment to these ever increasing complexities of life, is to court disaster. With the possible exception of a small percentage, man has no such power, and he automatically will escape when any situation becomes intolerable.

As an individual he will escape with alcohol, with repudiation of obligations, even with suicide. In the mass he will escape with calm repudiation of all debts, as we witnessed in Europe, or turn to a dictator when his load of responsibility becomes too heavy. But escape he will, even though he pull our pretty house down, and even though his apparent rem-

The Woman's Auxiliary

To the Medical Society of the State of New York

Albany County

The Woman's Auxiliary to the Medical Society of the County of Albany held its annual luncheon and meeting at the Albany Country Club on December 13, 1938. Mrs. Albert Vander Veer presided and welcomed the members and guests among whom were Mrs. G. Scott Towne of Saratoga, president-elect of the Woman's Auxiliary to the Medical Society of the State of New York, Dr. Otto Faust, president of the Medical Society of the County of Albany, and Dr. James Lyons, president-elect.

Mr. Dwight Anderson, Director of the Public Relations Bureau of the Medical Society of the State of New York, was the guest speaker and had as his topic "What Every Woman Knows."

Nassau County

The annual meeting of the Woman's Auxiliary to the Medical Society of the County of Nassau was held in the auditorium of the Nassau Hospital, Mineola, L. I. on December 27, 1938. Mrs. Luther Kice was elected president and Mrs. Arthur C. Martin first vice-president. The Auxiliary voted to give each high school in Nassau County one year's subscription to *Hygeia*. After the business session the members enjoyed a Christmas party. Mrs. Lally was hostess.

Onondaga County

The first meeting of the Woman's Auxiliary to the Medical Society of the

County of Onondaga was held in the recreation room of University Hospital on January 10. Mrs. Winthrop Pennock, newly elected president presided. Dr. Lopo de Mello of Buffalo was the guest speaker. A social hour followed the business session.

Queens County

The first meeting of the year of the Executive Board of the Woman's Auxiliary to the Medical Society of the County of Queens was held in the Medical Society Building on January 3. Mrs. William Lavelle greeted the members and asked for the co-operation of each member in order that the Auxiliary may carry on its work successfully. Plans and programs for the year were discussed.

Kings County

Our president, Mrs. Daniel Swan, was a guest at the installation of officers of the Woman's Auxiliary to the Medical Society of the County of Kings, held in the Medical Society Building on January 10.

ANNOUNCEMENT

The next meeting of the executive board of the Woman's Auxiliary of the State of New York will be held in Albany at the Hotel Ten Eyck on February 16, at one o'clock.

MILK ESSENTIAL IN A REDUCING DIET

One of the main ingredients of a successful reducing diet is a pint of milk daily, E. M. Geraghty, Baltimore dietitian, points out in her article, "Reducing Diets," in the January issue of *Hygeia*.

Often when a person decides to reduce his weight, he eliminates milk as one of the first

items, because he erroneously believes it is fattening. This is not true, the author indicates. Instead, it furnishes needed vitamins and minerals for repairing body tissues.

A pint of whole milk, skimmed milk, or butter milk or the equivalent should be averaged for daily intake, but butter, cream, and other fats should be kept at a minimum.

Medical News

Allegany County

Dr Jasper W Collier, of Wellsville, who died on December 29 at the age of eighty six had practiced medicine there for fifty-eight years. He was a former president of the Allegany County Medical Society.

Broome County

An interesting address on 'Higher Types of Pneumonia' was given before the Broome County Medical Society on January 10 by Dr A D Langmuir, Assistant Director, Bureau of Pneumonia Control, New York State Department of Health. He discussed the use of rabbit serum, sulfanilamide, and other refinements in modern treatment of pneumonia.

Cayuga County

The following officers were elected at the annual meeting of the Medical Society of the County of Cayuga, December 16, 1938: president, Louis F O'Neill, Auburn, vice president, H Donald Stuard, Genoa, secretary, Stephen J Karpenski, Auburn, treasurer, Robert J Thomas, Auburn, delegate to state convention, Harry S Bull, Auburn, alternate, Asel J Bennett, Auburn, delegate to 7th district branch, Donald M Green, Auburn, alternate, Walter B Wilson, Auburn, board of censors, Lillian A Treat, Auburn, Asel J Bennett Auburn, Howard I Davenport, Auburn, Frank L Okoniewski, Auburn, Roland J Walker, Auburn.

The guest speaker was Judge Richard C S Drummond. His subject was "Old Auburn," and he gave an interesting talk on the founding of the settlement by Col John Hardenburgh, which later developed into the City of Auburn. He also complimented the society on the historical data it has amassed, one of the most complete collections in the state.

Chautauqua County

The annual election of officers of the Chautauqua County Medical Society on

December 14 resulted as follows: president, Dr DeF W Buckmaster of James town, vice president, Dr Harry E Wheelock of Fredonia, secretary, Dr Edgar Bleber of Dunkirk, treasurer, Dr Frederick J Pfisterer of Dunkirk, Dr Clive E Hallenbeck of Dunkirk, the retiring president, presided. A lecture on head injuries was delivered by Dr Robert P Dobbie of Buffalo.

Chemung County

The Chemung County Medical Society, in co-operation with the Elmira Council of Social Agencies, is making an exhaustive survey to determine the needs and extent of medical and dental care throughout the county.

Questionnaires have gone to physicians, dentists, hospitals, industries, schools, public and private relief agencies, pharmacists, and lodges.

More than 500 information sources will be contacted in the survey, to be conducted in connection with the national movement of the American Medical Association.

The survey will seek to obtain a composite picture of the adequacy of medical and dental services. Co-operation of those to receive schedules is requested by Dr Elliot T Bush, president of the County Medical Society, in a letter accompanying the questionnaires.

Chenango County

The following officers were elected for 1939 at the annual meeting of the Medical Society of the County of Chenango on December 13: president, Don U Gould, Sherburne, vice-president, Mat G Boname, Oxford, secretary-treasurer, John H Stewart, Norwich, legislative committee, George I Manley, Norwich, economics, Edward Danforth, Bainbridge, public health, Albert H Evans, Guilford, maternal welfare, Eugene A Hammond, New Berlin. Dr Stewart has served as secretary and treasurer since 1917. At the scientific session a review

of recent literature on "The Use of Sulfanilamide" was presented by Dr Lyster Professor F J O'Connor of the Syracuse Medical College discussed "Otitis Media in Children "

Clinton County

At the monthly meeting of the Clinton County Public Health Nursing committee of the Board of Supervisors, Dr Elmer Wessell, recently elected president of the Clinton County Medical Society, spoke on the care of the expectant mother and the unborn child

In presenting the problem, Dr Wessell said "It is common knowledge that Clinton County has the highest per capita birth rate and it has also fallen heir to the highest infant death rate in the State of New York

"If this state of affairs is not necessary, it is abominable, and some attempt should be made to try to correct it, not for the sake of the figures, and the position of Clinton County, but because these figures mean that prospective mothers and the prospective children do not even get as good a chance as the worst in the rest of the state It means that our wives and future children have less chance of making the grade in confinement and birth than those living under the physical and educational environment at its worst elsewhere The problem and the challenge to us and to the general public, the medical profession, hospitals, town and county organizations, is to do something to improve this sorry circumstance "

Cortland County

Dr Merle R French, county health officer, was elected president of the Cortland County Medical Society at the annual meeting held at Cortland Free Library on December 16

Other officers elected for the year are Dr Robert Fairchild of Marathon, vice-president, Dr D R Reilly, re-elected secretary, and Dr B R Parsons, treasurer Members of the board of censors are Dr Hugh Frail of Marathon, Dr J E Wattenberg, Dr F F Sornberger, Dr C E Chapin, and Dr A M Loope

Dr Reilly was elected delegate to the New York State Medical Society Dr William A Wall was elected alternate

Erie County

A warning to physicians that their economic destiny depends upon their success in the coming year in working for "free choice of physician and less practice of medicine by hospitals" was sounded by Dr Harry C Guess, retiring president of the Medical Society of the County of Erie, in his farewell address at the society's meeting in Hotel Statler, Buffalo, on December 19

"Free choice of physician and less practice of medicine by hospitals must be our aim, not alone in staff room talk, but in fact," Dr Guess said "It behooves every member to give this some thought

"Regarding the care of the certified medical indigent, we will be on the spot, and many, not too friendly, will watch with particular interest the working of our plan

"Each member of this Society must remember that he is acting for the whole profession as well as his own livelihood

"Free choice of physician is the crux of our future destiny Lose that and we lose all

"Indigency is here to stay, let us do our part as always, for the care and comfort of the unfortunate By the same token, we should not play ostrich when some with a socialized think-tank would classify us as everything but what we are "

The following officers were elected for 1939 president, Carlton E Wertz, Buffalo, first vice-president, Herbert E Wells, Lackawanna, second vice-president, Nelson W Strohm, Buffalo, secretary, Louise W Beamis, Buffalo, treasurer, Roy I Scott, Buffalo, board of censors Harold F R Brown, Buffalo, E Dean Babbage, Buffalo, Joseph D Godfrey, Buffalo, Frank Meyers, Buffalo, Charles W Bethune, Buffalo Joseph C O'Gorman, Buffalo, was named chairman on legislation, John D Naples, Buffalo, public health, Harvey P Hoffman Buffalo, economics, and Allen R Long,

next extra Sunday or holiday and so on down the list.

A call to any doctor's office will be relayed to the one in town

Kings County

These officers were chosen for 1939 at the annual meeting of the Medical Society of the County of Kings on December 20 president-elect, Daniel A McAteer, vice-president, Albert F R Andresen, secretary, Thomas B Wood, associate secretary, Benjamin M Bernstein, treasurer, Maurice J Dattelbaum, associate treasurer, Benjamin Koven, directing librarian, Jaques C Rushmore, associate directing librarian and curator, Edwin P Maynard, Jr, trustees for five years, Charles A Anderson, John J Masterson, John B D'Albora Dr Philip I Nash, president-elect, became president on January 1, and will be succeeded next year by Dr McAteer

The program at the scientific session included

Address "The Diagnosis and Management of Breech Presentation and Delivery," Norris W Vaux, M D, Philadelphia

Address "The Diagnosis and Treatment of Menorrhagia and Metrorrhagia," Joseph L Baer, M D, F A C S, Chicago, Ill

The South Brooklyn Medical Society held its twelfth annual meeting on December 8 at Felzmann's, 39th St and 4th Ave Eighty-five physicians held a scientific session, elected officers for 1939, and feasted on beefsteak Dr Harold T Hyman, Dr John J Hauff, and Dr Lowell B Eckerson provided the speeches for the scientific program The officers elected were Dr L Walter Pearson, president, Dr George Sheehan, vice-president, Dr Julius Schlein, secretary, Dr J Parker Talmadge, treasurer, S Peter Barracca, counsel The beefsteak supper was served through the courtesy of William Neegaard, South Brooklyn pharmacist

Seventy physicians attended the December meeting of the Ridge Boro Medical

Society at the Shore Road Hospital Dr M C Myerson and Dr M S Ittleson provided the subject of discussion for the scientific session

The business session included election of officers and committees for the coming year, discussion of community economic and welfare conditions, selection of topics and speakers for the scientific sessions, and reports on the annual dinner dance and reception which is to be held at the Murray Hill Hotel on February 18 Part of the proceeds of the dances is to be donated to the Physicians Home of New York

The election of officers resulted as follows Dr William Ostrow, president, Dr Moses Silverman, vice-president, Dr Robert Princer, treasurer, Dr Ermente Torregrossa, recording secretary, and Dr Marcus Wiener, corresponding secretary

In recognition of his thirty years practice as a physician and surgeon in the Saratoga and Bushwick sections, Dr Philip E Smith, of 705 Macon street, was given a testimonial dinner, Wednesday evening, January 18, at the Hotel Martinique, 33rd Street and Broadway, Manhattan Members of the surgical staffs of the hospitals with which Dr Smith is affiliated, including the Bushwick and Evangelical Deaconess Hospitals, arranged the affair Assisting were a legion of his friends active in fraternal, veteran, and social circles

Madison County

In spite of vigorous protests by the officers and members of the Madison County Medical Society and by representatives of the Home Bureau units, Stockbridge Valley P T A, organized labor, Madison County League of Women Voters, county dependent children's committee, and Madison County Tuberculosis and Public Health Committee, the appropriation for continuing the public health nursing service in 1939 was eliminated in December by the county Board of Supervisors

Dr Richard B Cuthbert, Canastota, president of the Medical Society, said that

the Society was in deep sympathy with economy, "but we do not feel it is economy when it starts with public health. That is false economy. To eliminate the service means that expenses of welfare, hospitalization, pneumonia campaign and treatment of tuberculosis will be increased."

Dr Lynn B. Chase, Morrisville, Chairman of the County Public Health Nursing Committee, said "Loss of the nursing service would put the public health program back twenty five years." As to tuberculosis work, he said "It means the work will revert back to where only advanced cases are discovered. It is hard for physicians to diagnose early stages of the disease without the x ray. This has been done through the clinics. It also means no patients will be returned from hospitals as cured. Patients will also be obliged to look after their own care or that which the Welfare Department will give."

The nursing committee was organized in 1932. It went out of existence December 31.

Clinics to be given up because of no nurses to assist, according to the committee's statement, are Tuberculosis, toxoid for immunization against diphtheria and small pox, maternity, prenatal, preschool, nutrition, vaccinations, orthopedic, mental, child guidance, social hygiene, group education, and pneumonia control.

Monroe County

Dr Clarence V. Costello was made president of the Medical Society of the County of Monroe as successor to Dr Leo F. Simpson at the annual meeting on December 20.

Other officers elected are vice president, Dr Albert D. Kaiser, secretary, Dr William A. MacVay, and treasurer, Dr John J. Rooney. Serving with the officers on the board of governors will be Drs Warren Woodin, Benjamin J. Slater, Joseph P. Henry, John J. Finigan, and Edward G. Whipple. Drs Paul Beaven and H. C. Soule were named members of the Medical Milk Commission.

Dr E. T. Wentworth, reporting on a study being carried on concerning non-profit medical care insurance, said the county society will co-operate with the State Medical Society in seeking amendments to the insurance laws to provide for medical care through insurance.

He declared the physicians are not going to be stampeded by talk of compulsory health insurance—that a program will be worked out.

Guest speakers were Dr William A. Groat, of Syracuse, president of the State Society; Dr Peter Irving, secretary and general manager, and Dr Joseph Lawrence of Albany, executive officer.

Rochester needs a permanent eye clinic for poor children and others who are unable to pay.

This declaration is made by Dr John F. Gipner, chairman of the committee on eye defects of the County Medical Society. He said the \$2,000 authorized by the city to pay the cost of 1,000 children's eye examinations is inadequate. Continuing, he said:

"During the past year the County Medical Society for the fourth year in succession made a contract with the city government to examine the eyes of 1,000 indigent school children referred by Health Bureau nurses.

Seventeen physicians engaged in this service completed December 1, and already the hospital eye clinics report a growing waiting list for appointments.

It is evident that the present eye-clinic service cannot meet the need and therefore the need for a permanent, rather than an emergency plan, is being called to the attention of the city manager, the health officer, and the commissioner of public welfare."

Plans for a medical museum in the new building of the Rochester Academy of Medicine are in process of formation. Committees have been formed to develop divisions dealing with rare books and documents, plastic and graphic arts, instrument making and historical development, and pathologic anatomy. Courses

of instruction for the committees have been arranged with the librarians of the city, and the university and the Rochester Museum of Arts and Sciences is co-operating. The academy wishes especially to compile the medical history of Monroe County. Dr Morris E Missal is secretary of the museum committee.

Montgomery County

The following officers were elected for 1939 at the annual meeting of the Medical Society of the County of Montgomery, held December 14, 1938: president, Lew H Finch, Amsterdam, vice-president, Seymour L Homrighouse, Amsterdam, treasurer, Roger Conant, Amsterdam, secretary, William R Pierce, Amsterdam, censors, Robert C Simpson, Amsterdam, William H Seward, Amsterdam, William R Rathbun, Canajoharie.

Says the *Amsterdam Recorder Democrat*: "The re-election of Dr Pierce recalls that for thirty-five years he has served the society as secretary in a thorough and efficient manner, his painstaking efforts being in a large measure responsible for the success of all undertakings of the society and prominence given activities of the organization. Dr Pierce richly deserves the fine appreciation his colleagues always express in return for his constant labors well done in the office he has held so long."

Nassau County

The Nassau Surgical Society met at Meadowbrook Hospital on January 9 and listened to the following program: 1 Case Reports (a) Total Colectomy for Carcinoma and Polyposis, C A Hettesheimer, M D, Discussion opened by M R Jackson, M D, (b) Congenital Stenosis of the Bile Ducts, C A Hettesheimer, M D, Discussion opened by J W Bulmer, M D, (c) Horseshoe Fistula, G L Fair, M D, Discussion opened by E W Barber, M D, (d) Extensive Avulsion of Skin, Muscle and Bones of Foot, G L Fair, M D, Discussion opened by W L Sneed, M D, (e) Foreign Body in the Intestinal Tract, J B Conolly, M D, Discussion opened by C B Corbett, M D.

2 Paper Osteomyelitis of the Skull and Brain Abscess, J E J King, M D.

New York County

The New York County Medical Society, at its December meeting, adopted a resolution indorsing the Burke bill to provide salaries of \$680 a year for the 500 or more interns in the city hospitals.

The resolution, adopted by a more than two-thirds majority, put the society on record to "indorse the Burke bill for interns, prevail upon the co-ordinating council to have other county societies in the greater city to pass similar resolutions of indorsement, and employ its good offices in persuading the Council, Board of Estimate and the Mayor to carry into life this adopted principle of the society."

Interns in city hospitals now receive only \$15 a month and maintenance.

Dr Roy Graham Hoskins, of the Harvard Medical School, will speak on "The Story of Mental Diseases" at the New York Academy of Medicine on February 9 at 8 15.

Dr Eugene F Traub addressed the Society of Medical Jurisprudence at the New York Academy of Medicine on January 9, on "Dermatology in Court."

Dr Louis I Harris, formerly Health Commissioner of New York City, died on January 6 at the age of fifty-six. He founded the department's division of Industrial Hygiene.

Dr George Van Ness Dearborn, a neuropsychiatrist who for many years was connected with the Veterans' Administration, died on December 12 of a heart attack. He was sixty-nine years old.

Dr Henry W Berg, an authority on diphtheria and smallpox, died on December 22 at the age of seventy-nine. He had practiced medicine in New York City fifty-seven years.

Dr Henry B Cogswell, who had practiced medicine for fifty-five years, fifty

of them in New York City, died on Thursday, January 5, of a heart attack at 229 West Seventy eighth Street, where he lived and had offices. He was seventy seven years old. He was active until the day before his death, having treated a number of patients in his office on Wednesday.

Niagara County

The following officers were elected for 1939 at the annual meeting of the Medical Society of the County of Niagara, held in Lockport on December 13, 1938: president, Harley U. Carmer, Lockport; vice-president, Robert P. Reagan, North Tonawanda; secretary-treasurer, Forrest W. Barry, Lockport. Board of censors: Robert R. B. FitzGerald, Chairman, Lockport; Russel H. Wixson, Niagara Falls; Emil T. Mueller, North Tonawanda. Delegates: Guy S. Philbrick, Niagara Falls; Richard H. Sherwood, Niagara Falls. Alternates: Forrest W. Barry, Lockport; Raymond W. Holt, Niagara Falls. The guest speaker, Dr. Renshaw, of the Cleveland Clinic, described the use of the gastroscope.

Onondaga County

The following officers were elected for the year 1939 at the annual meeting of the Onondaga County Medical Society held at the Onondaga Golf and Country Club on December 6, 1938: president, Leon E. Sutton, Syracuse; vice president, Brewster C. Doust, Syracuse; secretary, Dwight V. Needham, Syracuse; treasurer, A. Carl Hofmann, Syracuse.

The program of the Onondaga County Medical Society on January 3 included the following papers: "Infectious Mononucleosis," Dr. Earle E. Mack; Discussion opened by Dr. Albert A. Getman; "Filterable Virus Diseases," Dr. Arthur E. Harris; Discussion opened by Dr. A. C. Silverman.

Dr. Brooks W. McCuen was elected president of the Syracuse Academy of Medicine to succeed Dr. D. F. Gillette at a meeting on December 20 in the University Club. Other officers elected

are: Dr. P. K. Menzies, vice president; Dr. Floyd R. Parker, secretary; Dr. C. E. McElwain, treasurer; Dr. S. C. Ruhson, Dr. Mortimer G. Brown and Dr. Carlton F. Potter, trustees; and Dr. Gillette, Dr. Leo E. Gibson and Dr. Clyde O. Barney, council members.

"Collection and Preservation of Placental Blood for Transfusion Purposes" was discussed by Dr. Charles A. Gwynn and Dr. John B. Alsever. An experiment on this line is now being undertaken at Syracuse Memorial Hospital.

Praise for the physicians and nurses of Syracuse for their work in the treatment of pneumonia has been received by Dr. H. Burton Doust, commissioner of health, in a letter from Dr. Alexander D. Langmuir, consultant of the bureau of pneumonia control of the state department of health.

After praising the splendid work done by Syracuse doctors and the Visiting Nurses Association, Dr. Langmuir wrote:

"We are now analyzing the records received in the past year and I am sure you will be interested in learning that the standards of pneumonia care in Syracuse are among the highest in the state, as measured by the percentage of cases typed, the amount of serum given and the number of treated cases in which blood cultures are taken."

Dr. Doust said the physicians deserve the lion's share of the credit for this report, although much of the pneumonia control work is co-ordinated by the department of health.

Ontario County

The meeting of the Ontario County Medical Society on January 10 at the U. S. Veterans' Hospital in Canandaigua was featured by quizzes on "Affections of Skin and Mucous Membranes" and "Sedatives," each lasting forty minutes. The questions were handed in by the members. The leader of the first discussion was Dr. A. M. Crance, of Geneva, and of the second, Dr. Robert J. Stein, of Canandaigua.

Orange County

Dr H F Morrison, of Tuxedo Park, was made president of the Orange County Medical Society at the annual election on December 13, followed by the selection of Dr Daniel I O'Leary as vice president, and the re-election of Dr Earl C Waterbury as secretary-treasurer. Other elections were Board of censors Drs Edgar Cuddeback of Port Jervis, S B Schleiermacher of Newburgh and Walter Hiresmann of Central Valley, delegates to state society Dr M R Bradner of Warwick and Dr H H Snyder of Newburgh, delegates to first district branch Dr R W Thompson of Cornwall-on-Hudson and Dr Frank Myers of Slate Hill.

More than seventy-five members heard Dr Frederick Elliott of Brooklyn, secretary of the Medical Research Association, speak on "Prepayment for Medical Care by Insurance," a plan similar to the United Hospital Fund. Dr Theodore West of Port Chester, president of the First District Branch, was also a speaker.

Oswego County

Dr K Wood Jarvis, newly re-elected president of Oswego County Medical society, has called the attention of the members to an address given by Dr Peter Irving, secretary of New York State Medical Society, before the Rotary Club of New York City. In this talk Dr Irving advocated medical indemnity insurance for voluntary prepayment of doctors' bills, as an alternative to state-controlled compulsory health insurance. This expresses the policy of the Oswego county society, Dr Jarvis explained.

At the December meeting of the county society, Dr Jarvis stressed the importance of all physicians being more active as citizens in their respective communities, and taking more interest in civic affairs. There was discussion on methods of improving distribution of medical care, not only to the indigent, but also to the economic middle class, to whom serious illness has become a difficult burden. The present American system of medicine can be retained, and better distribution of care can be given without resorting to

state control, the association members believe.

Otsego County

The Otsego County Board of Supervisors in December vetoed the proposed appropriation of \$28,000 for additional public health nursing service, after listening to Dr F L Winsor of Laurens, who told them that nearly 90 per cent of the doctors in the county were against it, and that the public health nurses, under the plan, would only instruct the family in what to do for the sick, and would themselves give little or no actual bedside care.

Putnam County

The new officers of the Putnam County Medical Society for 1939 are as follows: president, Ralph M Hall, Cold Spring; vice-president, Henry W Miller, Brewster; secretary, John T Jenkin, Lake Mahapoc; treasurer, Alexander Vanderburgh, Brewster; delegate, Henry W Miller, Brewster; alternate, E Roberts Richie, Brewster; censors, Garrett W Vink, Carmel, James L New, Carmel, Frank C Genovese, Patterson.

Queens County

Trustees of the Queens County Medical Society honored their chairman, Dr Edward A Flemming of Forest Hills, with a testimonial dinner at a restaurant in Richmond Hill, on December 15.

Dr Flemming has been a trustee for ten years and has served as chairman of the board for eight years. This was the first time in the history of the board that a chairman has been so honored.

Dr Fleming is a former president of the medical society and of the Queens County Surgical Society.

A demonstration in the diagnosis and treatment of pneumonia is being given at the Queens General Hospital by Dr William Benenson and staff, commencing Tuesday, January 10, and every Tuesday thereafter to and including Tuesday, February 28, between 3 and 5 P M. A

maximum of five registrants are received at each demonstration

Rensselaer County

The Rensselaer County Medical Society opened its program for the year on December 14 with a dinner at The Hendrick Hudson at which the officers were installed and an illustrated talk on "Surgical Curiosities" was given by Dr John F Erdmann of New York.

The officers inducted are Dr William T Shields Jr, president, Dr Charles W Hamm, vice president, Dr John F Russell, treasurer, Dr Leo S Weinstein, secretary, Dr Stephen H Curtis, Dr John D Carroll, delegates to the House of Delegates of the New York State Medical Society, Dr Clement J Handron, Dr George F Reed, alternate delegates, Dr William Trotter and Dr Charles H Sproat, censors.

Dr Hugh V Foley, outgoing president and toastmaster, acted as installing officer.

Sullivan County

The medical survey of Sullivan County, made by the County Medical Society, shows that no person is more than seven miles from a physician. Lack of adequate care is only due to failure of patients to use available facilities. As to cost, in one week in 1937, 17 per cent of the patients who received any form of medical service in home or office were treated entirely without charge, and thirteen free surgical operations were performed.

Tompkins County

The following officers were elected at the annual meeting of the Tompkins County Medical Society, December 20, 1938: president, Hudson J Wilson, Ithaca, vice-president, Harry G Bull, Ithaca, secretary treasurer, Willets Wilson, Ithaca, delegate, Norman S Moore, Ithaca, alternate, Leo P Larkin, Ithaca, censors C Stewart Wallace, Dryden, H L Van Pelt, Ithaca, David Robb, Ithaca, John F W Allen, Ithaca, J Wesley Judd, Ithaca.

Mr Carl Snavely, football coach at Cornell University, showed technicolor movies of the Dartmouth Cornell and Columbia Cornell football games.

Buffet lunch was served.

Warren County

That Warren County has an infant mortality rate of fifty five per 100,000, or an average of twenty deaths per 100,000 over the general state rate, was revealed by Dr Morris Maslon, director of the Warren County health activities, at a meeting of the Board of Supervisors on December 19.

Dr Maslon attributed the condition to lack of supervision and education of the public and said that a reduction of this rate is one of the main objectives of the 1939 county health program.

An increase in the treatment of communicable diseases such as tuberculosis, syphilis, cancer, and pneumonia was reported and an even more strenuous program was outlined for this year.

Dr Arthur W Chapman was elected president of the Glens Falls Academy of Medicine at a meeting at the Crandall Library on December 30.

Other officers elected are vice president, Dr J Leonard Byrnes, trustees, Dr Harold Peck and Dr Edgar Birdsall, committee on admission, Dr Stanley L Edmunds, Dr John Canaday, and Dr Saul Yafa, committee on public relations, Dr Leonard A Hulsebosch, Dr James Shields and Dr Dwight M Sawyer, library committee, Dr John Griffin, program committee, Dr William W Bowen, Dr Irving Juster, and Dr Morris Maslon.

The secretary treasurer is elected for five years and Dr William Bowen was elected to that office last year.

Westchester County

Four important scientific presentations are being given at the regular meetings of the Westchester County Medical Society. On January 17, Dr Byron Stookey presented a paper on Herniation of the

Nucleus Pulposus," a clinical study with lantern slides Discussion of Dr Stookey's paper was opened by Dr Joseph E J King of Bronxville

On February 21, Dr Samuel A Levine of Boston will offer a paper on "The Value of Auscultation of the Heart "

On March 21, Dr A H Aaron of Buffalo will address the Society on "The Treatment of Selected Gastrointestinal Conditions from the Viewpoint of the General Practitioner " Dr Aaron, who is the president of the Buffalo Academy of Medicine, presented this same paper last spring before the Ontario County Medical Society and it was called one of the greatest presentations ever given be-

fore that Society Dr Aaron also presented the same paper last summer at the seventh annual summer meeting of the Medical Society of Chautauqua County at Chautauqua Lake on a special program in which he was followed by Dr Menninger of Kansas and Dr Lahey of Boston

In April, Dr Perrin H Long of The Johns Hopkins Hospital, Baltimore, will address the Society on "Sulfanilamide," a subject in which Dr Long is nationally recognized as a leading authority This meeting will be held on April 18

All these meetings are at New York Hospital, Westchester Division, on the third Tuesday of the month

SUCCESSFUL WEIGHT REDUCTION OF 239 POUNDS

How a 32-year-old woman reduced from 395½ pounds to 156½ pounds in twenty months by dieting, with "progressive improvement in health," is related in the *Journal of the American Medical Association*

The woman had reached a top weight of 402 pounds before she underwent treatments at New York's Medical Center of Presbyterian Hospital, 168th St and Broadway

In addition to the diet, which permitted her a wide variety of nonfattening foods, the only treatment administered by Dr James J Short, of 502 Park Ave, was a daily dosage of thyroid extract.

Because of the 239-pound reduction in weight, an "apron of skin" was left over the woman's abdomen, Dr Short pointed out, adding that this excess skin, measuring 24¼ by 12¼ inches and weighing 5½ pounds, was removed by surgery

"The patient's health remained excellent throughout the entire period of reduction," declared Dr Short, assistant clinical professor of medicine at the New York Post-Graduate Medical School of Columbia University "At no time did she complain of hunger or weakness "

The secret of his success, Dr Short indicated, lay in the correct and varying dosages of thyroid extract, which he determined by mathematical computation of the woman's "total heat production," or energy output

Doctors, treating overweight patients, often consider only the person's "basal metabolism," which relates to heat production per unit of body surface, Dr Short said

It is essential, he asserted, that the area of the patient's body surface be taken into consideration in administering the thyroid extract

"The extent to which the metabolism rises depends on the degree of overweight and the consequent increase of surface area," his report stressed

For the guidance of other physicians, Dr Short presented a chart outlining his metabolism studies

"The case would indicate," he said, "that there is no limit in the extent to which excess weight may be removed by submaintenance diets, provided such diets contain adequate protein, minerals and vitamins, together with moderate amounts of carbohydrate

"Dairy products, such as skim milk and cottage cheese, are valuable in providing adequate calcium and phosphorus "

The patient was given no butter or bread and no sugar

Dr Short emphasized that the woman's overweight was not the result of any glandular or other physical disability Her father had been of normal weight, but her mother weighed 300 pounds, and one brother weighed 230 pounds

She was under Dr Short's treatment from March 22, 1935, until November 17, 1936

There was no scurvy in the Italian Army during the Ethiopian campaign, according to official reports Every soldier was given a lemon a day Ethiopian forces, on the other hand, are said to have had 30,000 cases

Hospital News

Million Volt X-ray for "Resistant" Cancer

A NEW x ray outfit, small enough for installation in existing hospital buildings, but designed to operate at 1,000,000 volts has been completed by the General Electric Company at Schenectady, for cancer research at the new Memorial Hospital building at Sixty Eighth Street and York Avenue, New York City. This new kind of x ray tube, equal to \$90,000,-000 worth of radium, is the result of discovery of a new electrical principle, say reports from Schenectady.

The tube was made for treatment of human cancer, but is also designed for industry, and gives both a new tool in cancer it furnishes an amperage, or volume of current, far in excess of any thing previously known.

For industry it is the first of these million volt giants that can be carried on a truck. Such rays, useful for looking through steel, have been available only for 'jobs' which could be transported to them.

But the million volt "eye" could be backed up to a structure like the Empire State Building, or taken inside and could look into the interior of the huge steel, concrete, and stone foundations that carry the load of the world's tallest skyscraper.

Effect Unknown As Yet

The tube was built by scientists of the General Electric Company's research laboratory for installation by the General Electric X ray Corporation. It will be placed this spring in the new \$4,000,000 Memorial Hospital, now nearing completion. This hospital is designed to be the world's most completely equipped cancer institute.

The director, Dr. James Ewing, one of the nation's ranking cancer scientists, says that the great amperage will be useful to try on 'resistant' types of cancer. "No one," he explained, 'knows what the effect will be because no such amperage has been available.'

The completed tube is a steel pill box, less than a man's height, with a lead tail projecting from its bottom. This tail is the lower end of a lead-encased bottle, which is the vacuum tube in which the rays are made. The bottle is 4 feet 8 inches long, much of it housed inside the pill box. The tail is the working end, where the rays come out for human use and industrial photography.

The new electrical principle enables this tube to use ordinary low frequency current. That is it could be plugged in on an ordinary sixty-cycle electric light socket. Previous tubes have required high frequency current, needing bulky apparatus to transform the power.

Old, Yet New

This one is really an old fashioned transformer, built on a new idea. Inside are more than 100 thin, flat coils of wire, built like huge pancakes with holes in their centers. They are stacked around the bottle-shaped tube.

In the old transformers the space occupied by the tube had to be taken up by a solid iron core. The core is eliminated by a new principle of balancing the number of coils with the frequency, that is, number of cycles per second, of the electric current used.

The result is a tube whose total weight is 4,000 pounds. Gone are hundreds of pounds of iron, thousands of pounds of the lead formerly needed to shield the tube and 12,000 pounds of oil which used to be required as insulation inside such a transformer. The oil is replaced by 100 pounds of the same gas used in mechanical refrigerators.

The first giant tube, ten years ago, developing only half a million volt x-rays, at California Institute of Technology, was nearly three stories high. In 1933, General Electric made an 800,000 volt tube which required a room 62 feet long, 32 wide, and 36 high.

When the Lights Go Out

WHAT THEN? How many hospitals are ready with emergency lighting? One of the leaders in hospital administration recently brought this vital point to the attention of the editor of *Hospital Management*, who declares this matter "should receive the attention of every administrator who has not yet made provision for an alternate source of light in case of power failure." We all know, he adds, that this emergency may arise, and fear that we may have a patient in the operating or delivery room for whom treatment cannot be interrupted. Yet many have failed to provide any emergency lighting because they cannot afford the more elaborate equipment. This course of action cannot be justified. There is more than one way of solving the problem.

Portable Lights

1 Candles and coal oil lamps. Candles can always be used and in some locations coal oil lamps are available. Both have the advantages of economy but neither can be used in operating and delivery rooms or in the emergency department because of the danger of explosion. They are, however, serviceable in wards.

2 Lights operated by dry cell batteries. I do not mean the ordinary flashlight because the small battery plays out too quickly. There are, however, larger lights operated by the standard dry cell which give a good light for quite a long time. They are suitable for operating and delivery rooms and for the emergency department if no better light can be provided. If supplied, they should not be neglected. They should be frequently inspected, at least three should be provided where two are necessary and there should be a supply of dry cells quickly available for changing. The reasons for these precautions are obvious.

3 Portable lights operated by storage batteries. These are next in increasing value of service. I do not

agree with those who advise comparatively high voltage for such outfits. The essential points are that the light is of correct power for the battery and that reflectors are of proper type, kept clean. Precautions to be taken are similar to those for dry cell lights. They should be inspected frequently and there should be a surplus of outfits for standby. In addition there should be provision for recharging the storage battery. This may be done in the hospital or, with the universal provision for recharging auto batteries, it may be safer and cheaper to use a regular recharging service.

Central Systems

4 Central system energized by storage battery. This is an elaboration of the portable system discussed in the preceding paragraph. A central set of batteries furnishes the voltage required and the current is carried to the points selected by a standard system of wiring. The system should be equipped with a recharging device and a voltmeter. An automatic switch puts the system into operation in case of failure of power.

5 Central generator plants. There are so many of these that any detailed discussion on this page is impossible. They vary from the large steam-driven plant to gas-powered equipment, the water wheel and the windmill type. Most have the advantages that many areas can be lighted at small cost, the plant can be run for an indefinite period in case of a long shutdown of the main source of power, and most of them can be automatically switched on. Their initial cost is not so great as is generally thought. Look into the possibility of one of these sources of emergency lighting with a local dealer.

The above is written merely to direct attention again to this important matter. I hope in the near future to present a full discussion of the whole subject by an expert, lighting engineer.

Now a "One-Cent-a-Day" Nursing Plan

AND all the other "plans" to pay hospitals and doctors at a few cents a day, Westchester County is slipping a plan to provide home nursing at \$3 a year per family, or a shade under one cent a day. Charles F. Neergaard, hospital consultant of New York City, tells about it in the *Modern Hospital*. It sprang from a gathering of leading spirits from various parts of the county, and is the fruit of more than a year of investigation, consultation, and constructive thought.

The program is tentative but, based on exhaustive findings, it is like this:

The Program

1 To offer a family membership with service to all members irrespective of age.

2 To limit service to patients attended by a private physician, which should effectively control abuse.

3 To furnish care to maternity patients for all illness irrespective of the stage of the disease.

4 To provide ten visits per family at an annual family subscription rate of \$3 a year (based on an average estimated need of two visits per year at \$1.40 each, plus administrative costs).

While the study indicates that the group plan applied to visiting nursing is needed, is desirable, and probably would be saleable, it has been felt from the beginning that it would be practical only if organized and offered to the public on a family basis as an extension of the benefits of the group hospitalization plan.

While the plan for visiting nursing service has not been officially presented to the trustees of the Associated Hospital Service, its director has participated in and several of its executives have kept in touch with the study, endorsed its objectives, and discussed ways and means of carrying out an experimental program to test its practicality.

To further the plan the Westchester County Nursing Council has been incorporated with a board of trustees composed of representatives of the various

visiting nurse agencies who will furnish the service as required.

What the Doctors Think

The secretary of the county medical society writes:

"The report and its conclusions have aroused a marked interest in the program on the part of all members of the Comitia Minora and an equally strong realization of the far reaching importance of your program and the potential benefits of a successful trial of the idea. In view of the importance of this proposal and the desirability of its receiving the most careful consideration, the Comitia Minora desires to devote considerable time to the study of this project through a special committee to be appointed in the immediate future." At its September meeting the society approved of the plan for the purpose of an experiment and requested the cooperation of its members.

As Nurses View It

The private duty nursing group, district No. 13 writes:

Several members of our board of directors have expressed interest and a desire to study the report. We would like to go on record as being interested in any future program which may be outlined as a result of this study."

A public health nursing executive writes:

Aside from the value for its intended purpose it is certainly a most enlightening study of our county work and brings to view many needs. I hope there will be tangible results in better nursing service for the people not only in Westchester but in many other communities."

Practical Details

Legal aspects are being investigated and a joint committee representing the nursing and hospital interests is to consider the many practical details that must be settled before it can be determined whether such a group prepayment plan can be offered to the public.

We are plowing a new field there are

many unknown factors, and definite actuarial figures are essential to any general adoption of the plan. It is the hope that, with Westchester County as a proving ground, a year's experiment

may be carried on with 5,000 of the 22,000 families, now members of the 3-cents-a-day hospital plan, to yield definite facts on demand, use, cost, and value of group prepayment nursing in the home.

Can the Very Small Hospital Be Justified?

SOMETIMES it can, but sometimes it is a menace, replies *Hospital Management*. "It is not the bed capacity which makes a hospital," the editor declares, "but rather the efficiency of the service it can render."

If it is to claim that it is a hospital, he goes on to say, there are certain prerequisites which cannot be ignored and among the first of these is laboratory and x-ray service. Modern diagnosis and treatment of any but minor disease conditions demand facilities and personnel in these specialty departments which are not economically possible in the very small hospital. If communication with a large center is good, this difficulty can be partially overcome, but the minimum that a hospital must have locally is a properly qualified technician for these departments.

Of even greater importance is the personnel. Nurses would, of course, be all graduate and, regardless of the number of beds, we think we are being conservative when we state four as a minimum if the institution is to function as a hospital. As a rule, nurses of experience will not go to the small community, but we believe the nursing profession will furnish the supply if such institutions are established only where there is an acute need.

The Greatest Problem

The greatest problem is the medical staff. The community which needs a hospital of less than twenty-five beds usually has only one or two physicians, but a surgical team for major surgery requires three physicians, an anesthetist, a surgeon, and an assistant. From the point of view of competence, the physician

in so small a community is not justified in attempting major surgery. He may have the best of training and may keep up-to-date in his theory, but he cannot have the continued and consistent practice which gives the necessary dexterity and judgment.

It is quite true that these principles are often ignored in the larger community but this does not negative the fact that they are right and should be observed.

Undoubtedly there are many isolated communities having a scanty population in which some provision should be made for the care of certain types of illness, and it will require a great deal of professional honesty and strength of character to limit service to that type of patient whose best interest is served by the small local institution rather than by sending him to the large center. This will include many medical cases, ordinary obstetrics, and surgery which is not complicated or extremely hazardous.

Put the Patient First

Our conclusion, based on experience and taking the above and other factors into consideration, is that occasionally a very small hospital is needed, but the best interests of the patient must be carefully considered in the decision to establish it and in its operation afterward. It is more than a first aid station, but it is not a hospital in the modern acceptance of the term. If it strictly limits its work to its capabilities, it will be a boon to the isolated community, but if it is allowed to become overambitious and unscrupulous, it will constitute a definite menace.

Newsy Notes

New York City hospitals and health are declared by Dr Haven Emerson, of the New York Board of Health, to be without equal anywhere in the world.

Dr Emerson, former New York City Health Commissioner, made his claims on Dec. 18 in reply to charges of overcrowding and bad working conditions before the final session of the New York State Temporary Commission to Formulate a Health Program, in the headquarters of the Association of the Bar of the City of New York, 42 W 44th St.

At a previous session, Mary Luciel McGorley, chairman of the health committee of the New York Industrial Council, had charged bad conditions and overcrowding in city hospitals.

Fourteen New York city hospitals—public and private—will be serviced this year by a central council of hospital libraries, the first organization of its kind to be staffed almost completely by volunteer workers. The set up is the work of the Junior League of New York in co-operation with the hospitals which will benefit by the services of sixty trained young women who combine a knowledge of the routine of book circulation with the more highly technical grasp of bibliotherapy.

In the Mental Health Clinic at Bellevue Hospital, New York City, the staff are now using metrazol in early cases of schizophrenia. "If it should become possible to use metrazol extensively in out patient clinics for early cases of schizophrenia," the report declares, "the result would be to revolutionize the whole treatment of this mental disease which alarmingly fills one-fourth of all hospital beds throughout the country. Such treatments are relatively inexpensive and are far simpler than time-consuming shock treatments with insulin."

An important change in the Associated Hospital Service of Western New York

has been made. While formerly twenty-one days of free hospitalization service were given to patients, with a 25 per cent discount on additional days in the hospital, the allotted period has now been extended to thirty days with an allowance of 33 1/3 per cent granted on the bill for the remaining time that the patient is confined to the hospital.

The bequest of \$100,000 to the Tarrytown Hospital in the will of the late Edward Benedict Cobb, former resident of Tarrytown, who died on November 24, must be used for the endowment of beds in the maternity ward for charity patients.

Persons close to the hospital expressed regret, after studying the will, that the institution's Board of Directors had not been given some discretion in the use of the \$100,000. A new maternity ward is badly needed.

The threatened closing of Oak Mount Sanatorium at Canandaigua has been averted and it will remain open for at least another year.

Establishment of a cancer clinic at Oneida County Hospital is recommended by Dr Robert L. Bartlett, superintendent of the institution. Dr Bartlett has informed the board of managers that the new annex contains ample room for installation of x ray equipment, and adequate accommodations for patients before and after treatments.

A new respirator has been presented to the Schenectady City Hospital by the auxiliary of General Eugene Griffin Camp, United Spanish War Veterans.

The Hudson City Hospital's request for an increase in the day rate for Co-

lumbia County patients from \$3 50 to \$4 50 has been granted by the Board of Supervisors

The late Mr George Doheny of Syracuse, a former president of Syracuse Savings Bank, willed \$147,932 93, which represents one ninth of his residuary estate, to St Joseph's Hospital in Syracuse. Other institutions, which shared equally in the residuary of Mr Doheny's gross estate of \$1,200,000, are Syracuse Memorial Hospital, House of Providence, St Vincent's Asylum, Syracuse Free Dispensary, General Hospital of Syracuse, St Mary's Maternity Hospital and Infants' Asylum, Onondaga Orphans' Home, and Syracuse Home Association.

Justice Cregg of Syracuse has ruled that the gift to St Joseph's Hospital was an outright gift, thereby permitting the hospital to use the bequest for the purposes stated in its charter instead of holding the fund as an endowment and being limited to use of the income for ordinary expenses of maintenance. The institution had made an application for a declaratory judgment that the bequest was an unrestricted gift, indicating at the same time that the hospital board desires to use some of the money for a reduction of a \$175,000 mortgage executed last year.

From now on, a subscriber to a non-profit hospital care plan in the states of Illinois, Missouri, Kansas, and Kentucky will not have to be a stay-at-home to derive full benefit from his membership. He can fall ill in any one of these four states, in any city in which there is a member hospital, with the comforting knowledge that he will be provided with the hospital care to which he is entitled.

The Mississippi Valley conference of nonprofit hospital care plans, organized in Decatur, Ill., on July 30, drew up its interchange care system, and the idea will be submitted to the American Hospital Association convention for possible adoption on a national basis—*Hospital Topics and Buyer*

Improvements

Utica State Hospital will construct a new printing shop and cold storage plant to cost \$200,000

The Swedish Hospital of Brooklyn will be the sole beneficiary of a three-day-and-night fair and bazaar to be held in the 106th Regiment Armory, Bedford and Atlantic Aves., on February 16, 17, and 18, under the auspices of fifty-one Swedish societies of Brooklyn in particular and the metropolitan area in general. Proceeds of the fair will be turned over to the officers and board of directors of the Swedish Hospital, to be used to complete the reconstruction of the six-story apartment house building at Bedford Ave and Dean St. as a new home for the institution.

A \$57,000 addition to the Kingston city laboratory marks the high spot in a WPA winter construction program for that city and Ulster County just announced by Lester W. Herzog, State WPA Administrator.

The laboratory was erected in 1936 by WPA and already has outgrown its quarters, so great have been the demands made on it not only by Kingston Hospital but other hospitals of Ulster County.

The addition will be of reinforced concrete and strictly fireproof.

The Board of Estimate of New York City has voted an appropriation of \$75,000 for reconstruction of the children's contagious disease building at the Queens General Hospital.

The action of the Board was taken after Dr S. S. Goldwater, Commissioner of Hospitals, stated that the present overcrowded quarters "are absolutely dangerous to the lives of the young patients."

Columbia County veterans have started agitation for a Veterans Hospital in that area.

A new nurses' home and female dormitory is to be added to the Neponsit Hospital in Queens

Samaritan Hospital in Troy has a new Cadillac ambulance.

Dr F Dixon Brown of Hobart is building a new hospital to accommodate six adults and two children

Westmount Sanatorium at Troy expects to put in new x ray equipment

Columbus Hospital, New York City, has begun construction work on a new \$100,000 addition Dr Charles R Borzilleri, president and founder of the thirty-year-old hospital, turned the first spadeful of earth The new fireproof wing will contain three operating rooms equipped with the latest facilities new electric elevators, and modernly furnished private and semi private rooms The capacity of the hospital will be increased to 150 beds

At the Helm

These hospital officials have been chosen

W W Smith to be president of the Malone Hospital Board re-elected

Dr Wayne B Henning, to be medical director of Stony Wold Sanatorium at Lake Kushaqua.

Dr Glenn R Ford, to be president, and Dr Roger D Meod to be chief of the surgical staff, of the Ideal Hospital at Binghamton.

Dr B A Fedde to be president of the Norwegian Hospital of Brooklyn, re-elected.

Dr Charles W Knapp, to be chief of staff of the Greenwich Hospital, reappointed

John G Nelson, to be president of the Lutheran Hospital Association of Brooklyn

Dr E P Russell, to be president of the staff of the Rome and Murphy Memorial Hospitals at Rome.

Dr Gregory L Robillard, to be surgical director of the Brooklyn Cancer Hospital

William H Barber, to be president of the directors of the Glens Falls Hospital

Harry Weinberg to be president of Beth El Hospital, re-elected

Dr F R Driesbach, to be president of the general board of the Dansville Hospital

Dr Robert J Wren to be president of the medical staff of Ossining Hospital

Dr E A Hammond, to be president of the board of managers of Brookside Crest Sanitarium at Sherburne

Mrs Rachael Israel to be president of the Westchester County Hospital Association

John Crane, to be superintendent of Physicians Hospital Jackson Heights

William D Entley, to be superintendent of the Arnot Ogden Hospital at Elmira

Dr Francis Giammattei, to be president of the medical staff of the Tarrytown Hospital

Dr H J Kruckerbocker, to be president of the medical staff of the Geneva General Hospital

Dr Victor A Bacile, to be chief of staff at St. Francis Hospital in Poughkeepsie

Mrs E C Hayward, to be president of the women's auxiliary of the Mount Vernon Hospital

Medicolegal

LORENZ J. BROSNAN, ESQ

Counsel, Medical Society of the State of New York

Malpractice-Failure of Proof in Fracture Case

THE highest court of one of the western states very recently passed upon a case which was brought against two physicians charging them with malpractice in the treatment of a fractured arm.* The fact situation involved presented a typical example of the results which may follow where in a difficult case the full co-operation of the patient is not obtained by the physician.

A six-year-old boy, while playing, fell and sustained fractures of both the radius and ulna of the left arm, and was shortly thereafter taken to a Dr. B. He requested x-rays and suggested that a Dr. A, who maintained a hospital also be called in the case. That day after x-rays were taken, Dr. A assisted by Dr. B set the arm and applied a molded plaster-of-Paris splint, with the arm at about a right angle. X-rays after operation showed good position of bones.

Although advised to leave the child at the hospital, the parent took the boy home the same day. The father was told to get in touch with Dr. B for anything that might be needed. The second and third days after the cast was applied, Dr. B did attend the patient and administered hypodermics for pain. He did not loosen or remove the splint. On the fourth day the child was taken back to Dr. A and the cast was removed. Some blisters were found which were treated and the splint was replaced. Again hospitalization was requested by Dr. A but declined by the father. Finally two days later (six days after original injury) the child was allowed to remain at the hospital under Dr. A's care. While there the splint was removed and the arm dressed and placed on a pillow. There was good circulation and movement in the wrist and fingers. A high temperature receded practically to normal. However,

at the end of forty-eight hours, the father insisted upon taking the patient home, although advised that the patient was not ready for discharge. Dr. A dressed the arm so that he could be moved, and from that time when taken from the hospital, Dr. A saw nothing further of the patient.

Dr. B apparently had little or nothing to do with the case from then on, and in ten days a third physician, Dr. C, was consulted by the parent. From that time he remained under the care of Dr. C and later also of a Dr. S who treated him from time to time for a condition of osteomyelitis which developed. The eventual result was a bad one, involving paralysis and contracture.

A malpractice action was brought on behalf of the infant and the father against Dr. A. and Dr. B. in which the charges of neglect were (1) negligence in attempting to set the broken bones, (2) that the flesh was not protected when the cast was applied, (3) that the arm was bound too tightly, stopping circulation, (4) that the cast was permitted to cut into the flesh, (5) that unskillful care of the arm caused it to become diseased and inflamed, and (6) that defendants refused to properly treat and dress the arm.

Upon the trial, numerous witnesses were called on both sides. There was a dispute as to whether the cast when applied was applied directly to the arm or whether it was lined (as defendants contended) with gauze. Of particular importance was the testimony of Dr. S, the orthopedic specialist who finally cared for the child. He said in the course of his testimony

" I was present in the court room when Dr. A testified, and heard his testimony. His testimony indicated proper treatment for the

* Brown vs. Dark, 119 S.W. (2nd) 529

type of injury involved Gauze or padding between the splint and arm is not always used In applying casts in the last eight or ten years, we have been using skin tight casts—a cast which is applied directly to the skin This is well recognized in Europe and this country, and we used it ourselves.

"Q What would you say, Doctor, if there had been no gauze between the splint, and the arm—would you say this is proper?

"A I would say that it would, and has been customary for me to use it in many cases

Volkman's paralysis is a degenerative change which takes place in the muscles and nerves and soft tissues of the arm and results in damage to circulation as a general rule. This paralysis can result from a number of different causes It may be the result of a direct injury to the blood vessels of the arm when the blood supply is cut off to the muscles, this degenerative change occurs following that. It may be due to hemorrhage or swelling within the fascia covering of the arm Muscles and deep structure are cased in a fasciae formation which binds them together It may be due to stricture, due to splinting, or pressure.

"From the condition of the patient disclosed by the testimony and from the condition which I saw on May 10th, I would not be able to tell the original cause of the trouble Assuming the important conditions which have been mentioned in regard to the circulatory condition—presence of radial pulse which indicates blood is being supplied to the parts, and movement of the fingers—I would say that at the time the boy left the hospital there had been no serious or permanent interference, and with proper care from then on, the condition should have improved, and the patient would have recovered. The condition that caused permanent im-

pairment of the arm could have developed after March 12th (the date child left Dr A's hospital) From the testimony of Dr A It is my opinion that this case was handled well by him throughout the treatment of the fracture, both regarding the x-raying of it, the reduction of the fracture, the apposition of the bones, the type of immobilization which was used, and the instructions which were given with regard to the kind of precautions necessary "

The Trial Court permitted the jury to pass upon the case, and there was a verdict and judgment in favor of the plaintiffs from which the defendants appealed. The Appellate Court reversed the ruling below and directed that the complaint should be dismissed With reference to the sixth charge listed above, which made a claim of refusal to properly treat, the Court said

'There is no proof of refusal by either appellant to treat the patient. On the contrary, appellee says Dr B continued his services On Saturday and Sunday nights hypodermics were administered by Dr B and he also loosened the bandages A liberal construction of the allegation might be that in failing, prior to Saturday, to remove or loosen the cast, there was declination to give treatment, but it can hardly be said, in the light of appellee's own testimony, that Dr B was not exercising his best professional judgment, even though he may and perhaps was in error in not undertaking to give other relief Certainly Dr A. is not to be charged with a failure to render services when appellee regarded the one treatment or operation at Jonesboro as the final services A was to render, and so testified '

The Court noted that each of the other charges in the complaint related to the treatment rendered by defendants on the first day, and said with respect thereto

"There is testimony in the record to show that the cast was too tight when first applied. There is testimony that within a short time swelling occurred, and that proper treatment probably would have been to loosen the tension. Dr A cannot be charged with such failure, for he had no opportunity to act. Appellee says he regarded Dr A's services as having ended March 4th. His entire case, as reflected by his instructions, is predicated upon appellants' negligence and want of skill when the operation was performed.

"Our conclusion is that appellee

has failed to support his allegations with substantial evidence. This is a case where a layman took chances and experienced misfortune of a tragic nature. If the doctrine *res ipsa loquitur* applied, the judgments might be sustained. But it does not. Medicine and surgery are inexact sciences, and physicians are not guarantors of results. Our view is that permanent injuries to appellee's son were occasioned by appellee's own negligence or error of judgment in not leaving the patient with Dr A when it became apparent infection had developed."

JUST WONDERING

"We are wondering," remarks the editor of *The Journal of the Arkansas Medical Society*, "if other members recall the statement made in an address by President Roosevelt at the dedication of the Jersey City Medical Center on October 2, 1936

"The medical profession can rest assured that the Federal Administration contemplates no action detrimental to their interests. The overwhelming majority of doctors of the nation want medicine kept out of politics. On occasions in the past attempts have been made to put medicine into politics. Such attempts have always failed and always will fail."

Cheering words then, remarks the Arkansas editor, shall we derive the same comfort from them but two years later? While we cannot say that we give their opinions unswerving belief, it is of interest in this connection to note the following news comments:

"You can count on F D R to push these pieces of legislation next session, administrative reorganization, part or all of the National Health Program. Results of the fall elections will determine whether certain of the measures will be moderate or sweeping but unless Democrats take an unexpectedly harsh licking, all will be pushed in one form or another"—*Newsweek*

Has anyone heard from the Republican party? "Put it down that a long step toward establishing permanent free public medical relief will be taken by Congress, regardless of the elections. The drive for federal-state aid of 'medically needy' is backed by all the forces that make for success. The administration is behind it. Con-

gress has already blazed the trail. The opposition is not only unorganized, but demoralized and bewildered"—*Washington Whirligig*

How do you, as an organized medical profession, react to those words, "unorganized, demoralized, bewildered," continues this editor, and he asks

Have you made a complete inventory of medical needs and care in your county as the survey contemplates? Have you, as individuals and as county society organizations, approached your legislative representatives in an effort to present to them the viewpoint of organized medicine? Are the people of your county informed as to the disadvantages inherent in any plan for governmental intervention in medical care? Are you taking steps to preserve your rights and privileges as a private practitioner of medicine?

FOR FEMININE M D 'S

The Woman's Medical Association of the City of New York announces that the Mary Putnam Jacobi Fellowship of \$1,000 for one year post-graduate work is now open to women graduates of medical schools. Dr Anne S. Daniel of the New York Infirmary, 321 East Fifteenth Street, is chairman of the committee. The fellowship is open to any woman graduate of an approved medical school. Applications for 1939-40 should be filed with the chairman of the committee on or before April 1, 1939.

Across the Desk

Discomfort or Malaise from Bullets and Buzz Saws in the Brain

THIS is as good a time as any to remind a hasty and careless populace in stern tones that firing bullets into the brain or ripping it up with buzz saws may bring on a headache or cause a vague feeling of discomfort or malaise. True, cases are on record where the victim has seemed better, more cheerful, than before. People used to say that a man with a mental quirk had 'a maggot in his brain,'¹ and it may be in such cases that the bullet hit the maggot.

But no one should be misled by these instances. A maggot is after all a small target, and firing at him may only rouse him to greater fury. Policemen, of course, have training in marksmanship, and Da Costa² tells of an Atlantic City officer, suffering from melancholia, who fired a .32 caliber bullet into his brain in December, 1909, three days before Christmas, and by Washington's Birthday his melancholia had disappeared. A little later he felt strong enough to give up his constabulary strolls and go into real work as a stevedore.

Not Always Improvement

But he was a policeman. A Kansas physician, Dr. Cyril V. Black, reports in the November, 1938, issue of the *Journal*³ of his state medical society the case of a young man who entered the hospital in 1935 and remarked casually "I have been shot." He walked into the emergency room, climbed upon the operating table, and was about the coolest person present. His pulse and blood pressure were normal. It seems he had dropped his rifle while hunting, it had gone off and the bullet had penetrated his brain, breaking into several fragments. These were not removed, but there has never been any evidence of infection, and he is now able to earn his living, three years after the accident by ordinary labor, al-

though his manual skill is not what it was. We must not always expect improvement.

Some readers may remember the case of the young woman in Nevada, recorded here a few years ago, who fired a bullet directly through the frontal part of the brain, entering at one side and coming out at the other. She lost consciousness for a few hours, it is true, but in three or four weeks she was out of the hospital, and a little later was up and around the house, performing her household duties as usual. She has fired no more bullets, so the maggot is perhaps stunned or disabled.

Brain Not So Important, After All?

Really serious injuries are quite different. The January *News Letter* of one of the county medical societies makes this clear. A small boy we are told, ran a splinter into his toe and died in a few days. A barefoot girl stepped on a nail and met the same fate, a dairyman slammed a door on his finger and was dead in a week. Accidents like these should have attention at once. Health advisers on the radio warn us that everyone with the sniffles should get medical aid.

A cold in the head may portend tragedy, but a piece of cold lead or steel in the cranium may be merely a bother. Thus, in 1884, Noyes⁴ removed the breech pin of a gun $4\frac{1}{2}$ inches long, $\frac{1}{2}$ inch wide, from a patient's nose orbit and brain, where it had remained five months with out producing serious disturbance. Perhaps the man hadn't noticed it. Dr. G. W. H. Kemper relates the case of a breech pin of a gun $1\frac{1}{2}$ inches long removed from the brain, with complete recovery. It is not at all rare, in fact, for a surgeon to remove a large section of the brain and the patient feels better than he did before.

All this casts a bit of doubt on the real importance of our organ of intelligence.

¹ Mentioned somewhere in Shakespeare?

² J. C. Da Costa, N. Y. Med. Jour. Oct. 29, 1910.

³ Jour. of the Kan. Med. Soc. November 1938 p. 464.

⁴ H. D. Noyes, Am. J. Med. Sciences, July 1884.

If we can let various objects go tearing through it without making any particular difference, and if the surgeon's knife can lop off a piece here and there with actual benefit, is it perhaps possible that we are neglecting to use considerable areas, and are fumbling our way through life at only one-half or one-third brain power? Certain it is that our great geniuses, our men of volcanic mental force, wear hats little or no larger than the rest of us. What, then, is going on inside their skulls so different from run-of-the-mine mortals? If we could only find that out! The x-ray shows us where lie the bullet and the tumor in the brain, but the divine spark of genius eludes our search, and leaves no trace on the film. Perhaps these mental giants use all the brain, where the rest of us are content to use a fraction. This hints at interesting intellectual possibilities for all of us if we could learn how to bring the fallow areas into productivity.

Butting a Buzz Saw

A bullet in the brain is after all only a small piece of metal. It may be self-inflicted, or fired by a loved one of regular or casual status, a sort of bullet-doux, so to speak. But when a man bangs his head against a buzz saw and it rips his skull open for eight inches and sprays his brains all over the place, we might think that would be "something else again." Not at all. A little mishap like that cannot keep the American worker from his toil.

It was "J. P.,"⁸ aged 28, an American planing-mill hand in North Carolina who crawled under the table of a rip-saw to adjust a set-screw. The story doesn't say if the set-screw was adjusted satisfactorily, which was the important thing at the time, but J. P. forgot the saw making 2,500 revolutions a minute. He never forgot it again, for his head struck it full force, and it "literally split his head open from well down on the forehead diagonally across the head, a distance of eight inches, cutting through the scalp, bone, superior longitudinal sinus, mem-

branes of the brain, and considerable brain tissue." The cut was a quarter of an inch wide. J. P. came out from under the table, rose to his feet, and walked about one hundred yards before he collapsed.

Dr. Stringfield reached him within four or five minutes, and with the aid of another doctor dressed the cut, and he was removed to a hospital, where "considerable brain tissue oozed from the wound." If he had had a really serious accident, he might have been kept in the hospital for quite a time, but as he had had only his head ripped open by a circular saw and his organ of thought whipped up as an egg-beater stirs eggs for frosting a cake, he "made an uninterrupted recovery, and left the hospital the fifth week." He also "suffered very little showed no signs of paralysis or any bad after-effects," and "returned to work the eighth week after the injury."

The brain contains considerable albumen, so that a man who uses his brain well is called a "good egg," and one who uses it wrongly is called a "bad egg." Why the whirling saw did not beat up the albumen and cover J. P.'s head with icing was apparently not investigated.

The Classic Case

Many readers by now are thinking of the classic "American crowbar case." It wasn't a crowbar, but a tamping iron, 3 feet, 7 inches long, 1 $\frac{1}{4}$ inches in diameter, and weighing 13 $\frac{1}{4}$ pounds. A premature explosion drove it completely through the head of Phineas P. Gage, a foreman of the Rutland Railroad, on September 13, 1847, while he was charging a hole with powder for a blast. The iron was round, smooth, and pointed, and entered the brain behind the left eye, coming out through the dome of the skull. Earlier paragraphs may lead some to think that Phineas paid no attention to it and went on with his work, or laughed it off, but the truth is our watchword, so it must be recorded that "he was slightly dazed, but not at all unconscious." A bit surprised, maybe, but didn't want to miss anything. Taken to a hotel, he

⁸ S. L. Stringfield, J. A. M. A., Sept. 19, 1914, p. 1,025

dismounted from the conveyance without assistance and walked up a long flight of stairs. In the evening, after his wound was dressed, he was perfectly rational, but later, when the excitement was over, he was delirious a few days. After that, his recovery was rapid. He lost his left eye, but otherwise was as good as ever. No one, however, has tried to imitate him.

Hitch up the Horse and Buggy

The question of the proper procedure in cases of brain injury like these is intriguing. When the doctor asks "Have you any headache or dizziness?" and the patient shakes his head, if there is a sound like castanets, it may be the fragments of a bullet rattling around in the skull. An entire change in the doctor's manner of approach may well be worth considering, too. Public taste, as revealed in the list of "best sellers," has had a strange transformation or throwback, and has 'gone ga-ga' over the old family doctor of the time of Rutherford B. Hayes. This shift of the wind must not be ignored. The profession must keep public favor at this time when it is standing at the crossroads. A hasty survey of the current magazines shows "America at the Crossroads," "Europe at the Crossroads," "Democracy at the Crossroads," etc., so that pretty much everybody is there now,

and there is no danger of being lonesome.

But the old long whiskered doctor of horse and buggy days is now the favorite figure of popular fancy, and the doctor who wishes to set his sails to the breeze of the hour will perhaps do well to drive up to the patient's door in a vehicle of the vintage of 1880, rush into the house, lay the patient out on the kitchen table, boil the family axe, hucksaw, carving knife and fork, sheepshears and Aunt Tiddy's darning needle in the wash-boiler, and go at it in the style everybody seems to like so much. Don't forget to have the scene illuminated by grampa holding a kerosene lantern.

Another fine old custom was to pay the doctor in produce. Cabbages are now fetching \$3.50 a ton at the farm, and if the doctor's bill runs to \$70, say, the grateful patient can appear at the door to pay up with twenty tons of this delicate vegetable. It might not be such a bad bargain, either, for an inquiry at a New York City market the other day revealed that the retail price of cabbage on upper Broadway is six cents a pound. A resourceful doctor could certainly find someone to market his cabbages, and how much would he receive? \$2,400! A return to the good old days might be worth while.

W S W

FOR BETTER NURSING SERVICE

A thorough study of the professional nurses registries throughout the state for the purpose of improving nursing service in the promotion of better individual and community health is the objective of the 1939 program of the New York State Nurses Association according to an announcement by Marguerite K. Jacobsen, associate executive secretary of the association.

The study will be conducted by an experienced field worker supplied by the American Nurses Association which is the parent organization of the State Association.

'We are seeking ways and means to improve the service we give to the public through the elevation of our own standards,' Miss Jacobsen said. 'To carry out this work we recently held two institutes for registrars.

Registries are developing hourly nursing service in many communities in the state because it is found that often a patient needs only an hour or two of skilled care and may then be left quite safely to members of a household. There is a growing demand for this type of service.

If a nurse goes into a home from a professional registry the family may feel that she is all that she claims to be. These registries or bureaus are nonprofit organizations and they seek constantly to be of assistance to the nurse and the patient. In many instances they provide lectures and demonstrations in nursing technique to keep the nurses informed of the best methods for caring for the sick. This is done in co-operation with doctors and hospitals.

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

REVIEWED

Modern Surgical Technic. By Max Thorek, M D Three volumes Quarto of 2,045 pages, illustrated Philadelphia, J B Lippincott Company, 1938 Cloth, \$33 00

Volume I deals with general operative considerations such as the attitude of the surgeon to his art, postoperative considerations, sterilization, and anesthesia. Part two deals with surgery of the head and neck and plastic surgery. Volume II divided into Part three and Part four deals with surgery of the nerves, vessels, bones, breast, and chest, and Volume III divided into Part five and Part six covers the surgery of the abdomen and the pelvic region. This work is intended to stand between voluminous systems which often prove confounding and single volumes too abridged to offer detailed information

sufficient for the student and general surgeon. As the author states, there seems to be a genuine need for a succinct work on surgical operations, one which includes important advances in surgical technic and is sufficiently detailed to describe the procedures in all commonly performed operations. It is intended particularly for students, for general surgeons, and for those general practitioners who are occasionally called upon to perform emergency operations. Historical notes are included and the essentials of surgical anatomy are given preceding operative procedures. The operations are described by the step-by-step method for the benefit of the student. There is an abundance of illustrations which elucidate the text and which make

clearer the author's intentions. The operative procedures are selected from an enormous number of surgical procedures, and these give a comprehensive and authoritative picture of the status of modern surgical technique. A comprehensive Subject Index to the text and figures is appended to each volume. This work should thus be an invaluable reference for all general surgeons and to those limiting their practice to particular fields.

EMIL GORTSCH

Pharmaceutical Latin For Pharmaceutical Medical Dental and Veterinary Students and Practitioners, by Jacob S. Dorfman. Second edition. Octavo of 146 pages. Philadelphia, Lea & Febiger 1938. Cloth \$2.00.

This book contains one hundred and forty pages of declensions, conjugations, and vocabularies—specifically written for pharmacists, physicians, dentists, etc., who have no preliminary knowledge of Latin. A perusal of it by the practicing physician would discourage rather than encourage the use of Latin in prescription writing. It is, however, the most thorough treatment of the subject, and would serve as a splendid reference book.

CHARLES SOLOMON

The Chemistry of the Steroids By Harry Sobotka. Octavo of 634 pages. Baltimore: Williams & Wilkins Company 1938. Cloth \$8.50.

The present book is the second of two companion volumes. The first reviewed the physiology of the bile acids and lipides, and this one discusses the chemical aspects of the subject. The term "steroid" is meant to comprise sterols and steroids, i. e., sterol like substances.

After an historical introduction, the author describes various methods of structural research of steroids. These chapters are of especial interest to the investigator in organic chemistry. In the next chapters the chemical properties of various steroids, i. e., bile acids, sterols, hormones, carcinogens, are described. Over 400 structural formulas serve to illustrate the text.

The second part of the book is taken up with a classified catalogue of the steroids and their derivatives. This occupies 330 pages of the book, comprising its main bulk. The properties of over 3,000 substances are described. An excellent bibliography, covering over 68 pages, with an author and subject index completes the book.

This book is essentially a storehouse of information for the research worker, especially for those attacking chemical phases of the problem. The compilation of this information will save hours of tedious search through the literature, for which the author deserves our gratitude.

ALBERT E. SOBEL

A Synopsis of the Diagnosis of the Acute Surgical Diseases of the Abdomen By John A. Hardy M.D. Duodecimo of 345 pages, illustrated. St. Louis: C. V. Mosby Company 1938. Cloth \$4.50.

In this small volume which is in the nature of a synopsis the author has discussed in a concise fashion the acute surgical diseases of the abdomen. Although references to the literature have been omitted, the book should appeal to the general medical profession.

There are chapters on chronic disease of the intra abdominal organs which perhaps cannot be considered acute surgical disease.

The author has drawn largely from his own extensive experience, and has covered the subject in a manner which will meet with the approval of the profession.

Perhaps a chapter or two on diseases of the chest, especially referable to the heart, might have been added in order to make this volume complete. The differential diagnosis between acute surgical disease of the upper abdomen and coronary artery occlusion is not uncommon and should receive consideration.

IRVING GRAY

Practical Otolaryngology and Rhinology By Adam E. Schlanser M.D. Octavo of 315 pages, illustrated. Philadelphia, Lea & Febiger 1938. Cloth \$4.50.

The author is a Colonel in the Medical

Corps of the United States Army With military dispatch he proceeds with clarity yet brevity to cover a very difficult specialty of medicine Every phase of otolaryngology is considered, and the author's attempt at brevity makes this work so much the more illuminating and instructive The book was written primarily to fill a clinical need, and this is admirably done To his brother medical officer, stationed at some out-lying camp or district, the Colonel offers this work as a guide and for consultation

The author purposely omits details of anatomy and pathology, and concentrates his efforts in making this volume a clinical work which will fill the need so keenly felt by those who would render the patient a maximum service Throughout this volume one can sense the clinical experience of the author as he guides the reader, and lends a helping hand to avoid the pitfalls in the actual practice of otolaryngology and in combating the always present malingerer The discussion of deafness and the testing of hearing is unusually complete and well done, yet simple and readily understandable As a civilian we recommend this book to the general practitioner, the medical student, and to the otolaryngologist As a medical officer we suggest that this volume occupy as conspicuous a place as *Army Regulations*

SAMUEL ZWERLING

The Pituitary Gland An Investigation of the Most Recent Advances Volume XVII of a Series of Research Publications of the Association for Research in Nervous and Mental Disease Octavo of 764 pages, illustrated Baltimore, Williams and Wilkins Company, 1938 Cloth \$10 00

This volume is divided into three general subdivisions, dealing with anatomy, physiology, and general considerations Sections dealing with anat-

omy and physiology are particularly good The late Frederick Tilney has contributed a chapter on "The Glands of the Brain" with special reference to the pituitary gland

Virtually every possible phase of pituitary relationships is discussed The book is unusually well illustrated, 160 illustrations and 53 tables, being nicely spaced in slightly over 700 pages of reading matter

It is perhaps inadvisable in dealing with a subject concerned with endocrine factors to state that it is "up to date." We feel quite sure, however, that any purchaser of the book would feel well rewarded, in adding such a detailed analysis of "The Master Gland" to his collection

HAROLD R. MERWARTH

Tuberculosis Among Children and Young Adults By J Arthur Myers, M D Second edition Octavo of 401 pages, illustrated Springfield, Charles C Thomas, 1938 Cloth, \$4 50

Dr Myers has so firmly established himself as one of the foremost authorities on tuberculosis that any additional contribution to the literature by him must be eagerly welcomed This latest book *Tuberculosis Among Children and Young Adults* fully lives up to expectations It develops most clearly and logically the relationship between primary tuberculosis infection and the various paths along which such infection travels and its ultimate denouement in secondary reinfection, or adult tuberculosis The book embodies all the latest concepts of the pathogenesis of tuberculosis in childhood and adult life, and, of course, is most complete in its description of the symptoms and management of each specific type Any practitioner of medicine who wishes to keep abreast with the rising tide of knowledge on this complex subject cannot afford to be without this book

NEW YORK STATE JOURNAL *of* MEDICINE

VOLUME 39

FEBRUARY 15 1939

NUMBER 4

Editorial

The State Meeting

Judging by the interest already evinced in the Annual Meeting by physicians all over the state, it is advisable for those who plan to attend to make their reservations now. The State Meeting always brings a gathering of the membership in force. For many reasons this year should set a record attendance.

The Annual Meeting of the Medical Society of the State of New York is one of those rare occasions which may truthfully promise all things to all men. To those primarily interested in scientific study it offers a program of outstanding excellence, with lectures, clinical demonstrations, and technical exhibits combined to impart a maximum of practical instruction in the brief time available.

Politically minded members who desire to study the currents which are pushing practice in new directions and to participate in the formulation of professional policy will have ample opportunity to satisfy their interests at the State Meeting. At the Annual Dinner this year Dr Irving Abell, President of the American Medical Association, will discuss national medical problems. Dr William A. Groat, President of the State Society, will present the situation in New York and outline the policies which will govern his administration.

It has not been forgotten that a large number of physicians view the State Meeting as an opportunity for relaxation and play. For them and their ladies golf, card parties, and other social events have been arranged.

In addition, the Society will have two distinguished guests at the Annual Dinner who are incapable of instructing without entertaining or vice versa. Dr Logan Clendening has made the romance

of medicine live for the laity without sacrifice or distortion of scientific fact Alexander Woolcott—dramatic critic, author, actor—unforgettably enriches every subject on which he turns the brilliant light of his multi-faceted wit

For those who have not yet noted the date in their diaries, the Annual Meeting will be held in Syracuse from the 24th to the 28th of April

Monopoly by the Inferior

In the January issue of *America's Future*, Dr Charles Gordon Heyd asks the American public what kind of medicine it wants "Do You Want Your Own Doctor—or a Job Holder?" asks Dr Heyd, and in the asking he tells the laity what it may expect if compulsory health insurance drives out the private practice of medicine in this country

For sooner or later compulsory insurance does drive out private practice, with the inevitability with which "bad money drives out good" under Gresham's Law As the compulsory insurance system is expanded to bring in ever new classes of the population—and it must be so expanded to remain solvent—it becomes less and less possible for private practice to compete with cheap state services In the end, the government exercises "a complete monopoly in distribution of medical services"—a monopoly which is more real and more dangerous than the spurious charge trumped up against the American Medical Association by Assistant Attorney General Thurman Arnold and his cohorts

As Dr Heyd truly observes, compulsory health insurance is a political expedient rather than a scientific attempt to satisfy the medical needs of the public on a quality basis It promises service that it cannot possibly deliver, for while it undoubtedly spreads the cost of medical care, it can buy no more of the latter than "is provided by the premiums less the cost of administration The tax dollar for compulsory health insurance cannot possibly buy a dollar's worth of medical service for the solvency of the insurance system will eventually regulate costs at the expense of medical benefits "

The proponents of compulsory health insurance proselytize for their scheme by hammering away at a few striking sets of statistics Upon close examination, however, most of their figures are seen to be more sensational than accurate For example, they point to the number of deaths from tuberculosis in a given year as a sample of the inadequacy of our system of medical care, but they do not

say that the League of Nations' statistics show a more rapid decline of the tuberculosis death rate in noninsurance than in insurance countries. As a matter of fact, they avoid all mention of the tremendous drop in tuberculosis mortality which has taken place everywhere in the past quarter century, and which may reasonably be expected to continue.

On the subject of costs the friends of compulsory health insurance are equally vague, not to say misleading. Dr Heyd quotes Bower Aly, who promises complete medical care for *only* ten cents a day per person. That sounds cheap, doesn't it?—until a little multiplication brings the figure to \$146 a year for the average American family of four persons.

It must be emphasized in this connection that the money for compulsory health insurance would come in the main from the workers themselves. "There is no such thing as free medical service" under state control. "Taxes," generally speaking, "are paid by all of the people and not by the rapidly disappearing rich class. Every cent taken from the dollar for taxes is just that amount abstracted from the standard of living." If longer life and better health resulted from this sacrifice, it would be worth while, but the inescapable fact remains that on the whole the United States and Canada have lower morbidity and mortality rates than any country with compulsory insurance.

This is primarily because "the practice of medicine in America is a diagnostic practice, based upon complete physical examination and scientific laboratory determinations." In panel practice, with few exceptions, ambulatory medical care consists of "a brief visit to the doctor, an inadequate scant history and a prescription or the dispensing of a bottle of medicine."

Any system of state medical aid to be acceptable to the medical profession must conserve the best standards of private practice. "Organized medicine believes the health of the citizens is one of the primary interests of government. It does not believe, however, that the government can function in the distribution of medical services as well as those trained to render that service."

High Incidence of Unrecognized Trichiniasis

From several extremely impressive studies during recent years concerning the incidence of human infestation with the *Trichinella spiralis*, it is evident that this remains high despite the painstaking governmental inspection of meat which has been in force for the past forty years. Queen,* who conducted his survey in Rochester (New

* Queen, F. B.: *J. Parasitol.* 17: 123 (1931)

York) and Boston, found it to be 18.7 per cent. McNaught and Anderson* report the occurrence in their series as 24 per cent, while Pote,† working in St. Louis, found the larvae in 15.4 per cent of the 1,060 unselected autopsies. These figures are much higher than those existing in all reports prior to 1901, and therefore some important conclusions can be drawn from the work of these investigators.

In Pote's 163 positive observations there were instances of infestation to a severe degree, yet in no case was there any evidence of trichiniasis to be found either in the clinical picture or in the history. This is in accord with the findings of others who have conducted similar studies. Furthermore, the occurrence of the *Trichinella* was not found to be either a direct or a contributing factor in the death of these 163 patients. During the five-year period of Pote's study, only seven cases of trichiniasis had been reported to the Health Department of the St. Louis area, despite the large number in whom the parasite was found at postmortem examination.

Since in packing houses under Federal supervision, the law compels the processing of all pork products to destroy the *Trichinella* where there is a possibility that the pork may be eaten without cooking, the source for this high incidence of infestation must be sought for elsewhere. In all probability it is the "country pork" prepared on the farms and in unsupervised local slaughter houses that is responsible for the wide extent of trichinella infestation in man. Consumers of pork, regardless of its place of preparation should be warned to cook all pork thoroughly, since, in the last analysis, they alone can completely eradicate trichiniasis by strictly observing this counsel. A casual hint from the doctor to his patient will help a great deal.

Fresh Blood vs. Bank Blood

The clinician has never concerned himself to any degree with the details surrounding the administration of blood by transfusion. In the numerous conditions for which he prescribes blood he rarely interests himself beyond determining the need for such medication. Yet there are instances in which the direct transfusions of whole blood is infinitely preferable and of more therapeutic value than the use of citrated blood. Because of the widely spreading institution of "blood banks" in our hospitals, a tendency to use this source of supply as a routine one for all cases may manifest itself. As Rhoads and Panzer‡ point out, this stored blood is not equivalent to freshly drawn blood in all respects.

* McNaught, J. B., and Anderson, E. V. *J. A. M. A.*, 107, 1,446 (1936).

† Pote, B. *Am. J. Med. Sc.*, 197, 47 (Jan.), 1939.

‡ Rhoads, J. E., and Panzer, L. M. *J. A. M. A.*, 112, 309 (Jan. 28), 1939.

Using a modification of Quick's* method in order to determine the prothrombin time of blood stored in the bank, samples were examined ranging in age from three to ten days following withdrawal from the donor. It was found that the older the specimen, the greater the prolongation of the prothrombin time. This ranged from 17 per cent increase on the third day to 40 per cent on the tenth day. They conclude from their observations that the use of blood which has been in the bank more than a week is almost valueless in the treatment of diseases having an acute prothrombin deficiency. Where, for instance, it is desired to combat hemorrhagic tendencies in jaundiced patients both pre- and postoperatively, the transfusion of stored blood is decidedly less effective than freshly drawn blood even where bile salts and vitamin K had been given.

It is obvious, therefore, that the clinician must in the future be aware of the fact that the mere prescribing of blood is no indication that his patient will receive the quality of blood needed to meet the given situation. He must indicate the kind he wants administered, and, until the laboratory provides additional data on the comparative values and curative properties of bloods differently prepared, he will have to be guided by his bedside observations.

Current Comment

"The general idea of creating a big general fund through which the masses could get medical treatment at low cost is okay, and a humane proposition, if politics is kept out of the business of getting a doctor in a hurry. The danger is that you'd phone the Federal bureau for a bonesetter and get an eye doctor. And even then you might have to wait until eight or ten healthy bureaucrats got around to investigate your case to see if you were really sick. And if there is one thing most people would be scared stiff by it's the possibility of the Government ever being the one to see that the right labels get on the medicine bottles." The foregoing is from the column "Dave Boone Says" in the January 25, 1939 issue of the *New York Sun*.

candidates for medical schools suggested by politicians." from an address by Dr Charles Gordon Heyd

The chief protection of the American medical profession against becoming pawns in the hands of political strategists is the assumption by its members of roles of social leadership. Physicians have always been considered as insulated against all extra professional contacts, barred to civic interests, poor business men, impractical idealists, sentimentalists who are mercilessly exploited by professional welfare organizations. But they themselves are chiefly responsible for these poor opinions of them, they have been so busy in their own kitchen gardens that they have seldom looked upon the outside fields.

'If we have a system of socialized medicine, we cannot exclude the son or daughter of any politician. We will have

The earnest thought and endeavor of physicians will still be engaged with adolescence, senescence, casualties, and malignities but these will not claim their

* Quick, A. J.: *Am J Physiol.* 114: 282 (1935)

entire attention. Sickness and death are important, but not so much as life. Even life itself is not so important as its quality.

Theoretical and applied science must now be used not for the satisfaction of curiosity, but for the betterment of self and for the construction of truly civilized man. "Doctors Must Grow Up" is the title of an editorial in the *Medical Record* of January 18, 1939, from which we have quoted in part

. . .

"He (the doctor) is the man, at long last, who will be called upon to deliver the medical care which is the subject matter of proposed legislation, and if he knows good reasons why certain laws will work and others will not, he may properly see to it that they are presented to the men who make our laws. In fact, it may even be that his Senator and Congressmen are waiting to hear from him." "Write Your Congressman Immediately," recommends Dwight Anderson, Director of the Public Relations Bureau of the Medical Society of the State of New York, in the January, 1939, issue of *The Public Opinion Quarterly*, published by the School of Public Affairs of Princeton University.

. . .

"Is medicine a philanthropy depending for its support upon gratuities, or is it a profession at which the practitioner must work for his livelihood and economic position? It has been said 'By their works ye shall know them.' Upon that thesis *medicine* ought not to have to stand before the bar to plead. But the fact is, it must. Let us, then, be stiff-jointed advocates, who see the right, and speak with authority, unanimously." This time the call to stand together comes from the Toledo Academy of Medicine's *Bulletin*.

. . .

"It is probable that to the lack of careful thinking, or maybe the inability to

think clearly, a common fault these days, the world owes its present distresses, social and individual, a term too mild to apply to the upheaval which is taking place. If the task of bringing things into something like order is not taken in hand, and if force triumphs everywhere, the world will not only be unfit for heroes to live in but for ordinary people as well." From an editorial on "Our Civilization" in the *Medical Record* of January 4, 1939.

. . .

"The fact of the matter is that unless there is strict medical control of contract practice it is bound to be of an inferior type, employing unskilled or inexperienced physicians. It stands to reason that a system which pays enough to attract qualified physicians cannot be as cheap as interested persons would have us believe.

Medical service of a high-grade type cannot be 'thrown in' as a premium to promote sales memberships or circulation—as some newspapers, for example, have attempted to do. Neither can it be furnished at bargain prices of fifteen or twenty cents a call. It is distinctly not a mass production industry. The point is that group payment plans must observe the same ethical rules as govern the practitioner's relations to his privately paying patients. This entails fair payment for the doctor, avoidance of unethical advertising and soliciting and strict control of standards by organized medicine." An opinion expressed by the editors of the *St. Louis County Medical Society Bulletin* of January 20, 1939.

. . .

"So long as we find it necessary to invest sixty or eighty millions in a battleship which is obsolescent even before it is completed, and grant only a few millions for the study of cancer or mental diseases, militant science has a case." From an editorial in the *New York Times* of January 4, 1939.

TREATMENT OF DERMATOPHYTOSIS WITH TRICHOPHYTIN, CONVALESCENT OR IMMUNE SERUM, AND VACCINES

EUGENE F. TRAUB, M D, and JESSE A. TOLMACH, M D, New York City

IT is our belief that at this time dermatologists should come to an agreement as to the efficacy of the various biologic methods of treatment of dermatophytosis. We are all aware that vaccine and extract treatment of this disease has received wide use on the part of physicians on the basis of overenthusiastic reports partly in the medical literature and partly from commercial advertising. Perhaps a critical résumé of most of this work done to date would serve to stimulate dermatologists to take a more uniform attitude toward such treatment. After all, it is to the dermatologist that the general physician turns for the last word in the treatment of skin diseases.

It was logical that dermatophytosis, which is so prevalent and so persistent and which causes systemic reactions, should have been given thorough study from an immunologic standpoint. All of us have experienced difficulty in clearing up some of the mycotic eruptions with which we have been confronted and it is an even more common experience to see many of our "cured" cases return quickly with what were formerly believed to be fresh infections but which probably represent a relapse of a previously arrested but dormant infection. Therefore, trichophytin, when first used in this country as a therapeutic agent by Van Dyck, Kingsbury, Throne, and Myers,¹ appeared to place at our disposal a valuable form of desensitization therapy. They stated that "during this investigation, it was noted that recurrences or exacerbations were uniformly seen when the curative injections were not continued until there no longer appeared any reaction at the sites of injection, or, in other words, until a general desensitization had developed." Also that "sufficient time has

not elapsed to allow any conclusions as to the duration of the immunity which this method of treatment may produce." They apparently assumed that the desensitization and immunity paralleled one another. One hundred cases of "mycotic-like eruptions which gave a positive reaction to trichophytin" were selected and given trichophytin injections together with the usual local measures. They reported 32 per cent of their cases as apparently cured, 28 per cent greatly improved, 21 per cent slightly improved, and 19 per cent unimproved.

Sulzberger and Wise² following along the same lines asserted "Since the dermatophytids are today usually the most important therapeutic problem in the common tinea infections and since these 'ids' are dependent on the hypersensitiveness of the skin for their existence, attempted desensitization therapy was indicated. In 18 cases of probable 'ids' desensitization by means of intradermal injections of trichophytin was attempted. While complete or relative desensitization could be achieved in 15 cases, only about two thirds of this number seemed benefited by the treatment, these showing either long remissions or marked improvement or apparent cure." They selected 18 cases of "probable ids" (no microscopic or cultural identification having been done) and treated them with trichophytin and in all but 2 or 3 cases with the usual local remedies as well.

Kerr, Pascher, and Sulzberger³ reported on 6 cases selected in the following manner "Eczematous hand and foot eruptions clinically called dermatophytosis and dermatophytid (in the large majority of which it may be assumed that both the omnipresent *Monilia* and the almost omnipresent epidermophyton could

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 10, 1933.

have been found by careful mycologic investigation of the feet, toenails, mouth, et cetera) There were none with skin reactions to trichophytin alone, 8 cases with reactions to both trichophytin and oidiomycin, and 4 cases with reactions to oidiomycin alone." In other words all 12 were positive to oidiomycin. These patients were treated with either trichophytin, oidiomycin, or with both. Additional local treatment may have been employed, its use is not denied. Four of the cases were improved after varying numbers of injections (11-20), 1 case marked "cured" after ten injections had a relapse in six months and had improved after seventeen more injections. The last case also "cured" after five injections returned after eight months to receive eight more at which time the patient was discharged from treatment. Actually then, one of their cases may have been "cured" yet their conclusions were that "satisfactory therapeutic results, through desensitization either with oidiomycin alone or with oidiomycin plus trichophytin are reported in 6 persistent cases of clinical dermatophytosis and dermatophytid." Apparently they too, like Van Dyck, et al., thought that immunity and desensitization were necessarily one and the same process—to quote "moreover, just as in other active immunization procedures, we observed that in oidiomycin desensitization the *active immune* or *desensitized* stage may sometimes be reached by passing through a stage of increased hypersensitivity."

We found desensitization⁴ with trichophytin a very temporary affair. In a series of 135 patients treated with this agent, all of the patients whom we succeeded in desensitizing and who returned to us with recurrences showed the same reaction to trichophytin that they had shown before the first treatment was instituted. In our comments we said "We feel that desensitization as manifested by the failure to react to trichophytin, had little or no effect on the course of the disease. There was certainly no evidence to encourage us in the hope that immunity can be induced by

means of injections of trichophytin. On the whole, trichophytin had as little effect on the "ids," in which improvement might have been expected theoretically, as on the mycotic foci, in which it was not expected."

Osborne, Putnam, and Rickloff⁵ treated more than 100 proved cases of dermatophytosis with trichophytin and monilia extracts. Unfortunately they did not state whether or not local remedies were also used. Despite the fact that this article was published before our study, which was done at the same time, we overlooked this report because it was buried in an extensive review dealing with other phases of dermatophytosis. It is significant, therefore, that our conclusions and theirs, independently arrived at, are identical. They concluded, "our results have been sporadic and, we believe, no better than could have been expected without trichophytin. In chronic relapsing mycoses of the hands and feet our results have been very disappointing. Apparently good results, in most instances, proved later to be temporary. We should never forget the natural tendency to improve and relapse, depending upon the environment, and especially under mild antiseptic applications. We can find no theoretical reason for expecting that desensitization would effect a cure of a primary focus. Local flare-ups of foci and widespread dermatophytids, asthma, and urticaria have been observed following trichophytin and in one instance a severe vesiculopustular exfoliative dermatitis."

Templeton⁶ also warned that when using trichophytin, caution was necessary and he reported cases with severe local, focal, and general reactions to the orthodox, strong concentrations usually employed.

We⁷ discussed fully in another study the dissociation of hypersensitivity (allergy) and immunity, and advised, for purposes of clarity, the restriction of the term allergy to the following definition of Rich "that state of specific hypersensitivity which develops as a result of the entry of foreign protein into the tissues, and which

manifests itself locally by the occurrence of tissue damage and inflammation wherever the foreign protein or even a specific fraction of the sensitizing molecule (hapten) lodges in the previously sensitized tissues." Probably only the word 'protein' in this definition might be subject to revision. This dissociation of allergy and immunity noted by Rich, Kahn, C. A. Stewart, Cross, C. M. Williams, and others was demonstrated by the results we obtained in the treatment of our patients with trichophytin. In 83 of our cases in which microscopic identification was obtained we were able to desensitize 23 completely, but we did not effect a cure in a single instance. Sixteen patients in this series gave no reaction to trichophytin at any time, despite the positive mycologic findings and in this group there were 2 apparently "cured" cases, and 5 patients who showed improvement. In 52 cases in which microscopic identification was lacking, we were able to desensitize 17 patients, only 2 of whom were apparently cured.

It should be evident from the foregoing that even the most optimistic did not expect trichophytin to destroy the primary mycotic focus, but it was hoped that it might, by desensitizing the skin, eliminate the dermatophytid. This hope was not realized.

Our next step was to attempt treatment with what we chose to call 'convalescent or immune serum.' It had been shown by some investigators, though not unqualifiedly confirmed, that there are fungicidal elements in the blood of these patients. Per and Braude⁸ stated that 'parasitic fungi ceased growing within two days after being mixed *in vitro* with blood serum of allergic subjects.' Jessner⁹ also described "growth-inhibiting antibodies in the blood serum of patients hypersensitive to fungi." Ayres and Anderson¹⁰ reported a study which indicated the presence of circulating fungicidal antibodies in the serum of patients having "phytid" lesions associated with dermatophytosis. The latter authors contended that the presence of the antibodies was proved by the failure of growth of

fungi isolated from the primary focus of infection inoculated in Sabouraud's medium mixed with 8 per cent of the patient's serum.

Assuming the presence of these elements in the blood and assuming too, that there are not enough of these reaching the skin to prevent the growth of fungi in cases of dermatophytosis, we decided to attempt to put these hypotheses to a practical application.

We selected 14 cases of clinically typical and microscopically confirmed dermatophytosis with dermatophytids. We also selected 4 cases of confirmed dermatophytosis of the feet alone. The duration of the disease in these cases varied from a few weeks to several years. To each of these patients we gave subcutaneous injections of serum obtained from patients with fungus infections of the feet accompanied by dermatophytids, whom we had completely cleared of the eruption with the usual topical remedies. All the blood to be used for treatment purposes was first checked with Wassermann and Kahn tests. The blood was withdrawn just as soon as the eruption cleared. This was done for two reasons. First, we assumed that at this point the fungicidal elements, if present, would be at their maximum quantity. Second, we did not know how long they remained after the eruption cleared.

The serum was kept on ice and no preservative was added. After a period of two weeks, the serum was discarded because of the possible deterioration of these elements. The injections were given subcutaneously in doses of 1 to 3 cc. every five to seven days and an average of six injections was given to each patient. No local applications were prescribed. These considerations were entirely arbitrary.

The results proved of some interest. Three of the 14 cases of dermatophytosis with dermatophytids were completely cleared. Two of the 4 cases of foot infection alone were completely cleared. There were recurrences within a period of three weeks to two months in 4 of the 5 cleared cases. The fifth case disappeared from our clinic. In 16 of the 18 cases,

there was noted a very definite clinical improvement in both the hand and foot lesions after the first to the third injections. Also, it was noted that in most of the cases, after this initial improvement, the condition remained stationary. In 2 cases, no changes were noted.

The number of cases was obviously small. The difficulty of obtaining serum and having suitable subjects on hand at the same time is evident. The conclusions to be drawn from this experiment can only be speculative. It is possible that the few temporary cures and the general marked improvement after the first few injections were the result of supplying needed immune antibodies to the patients. It is conceivable that better results might have been obtained if larger doses of serum had been given. It is also possible that the early improvements were due to psychic factors, i.e., suggestion. In the latter respect, it might be pointed out that in the treatment of this disease with trichophytin injections we encountered many cases of early improvement followed by a more stationary course and even exacerbation. We observed this type of response in one case in which we injected only normal saline solution. Some of the improvement may have been due to nonspecific action. The answer to these speculations will depend on further painstaking investigations of this problem.

At the same time Robinson and Grauer¹¹ were treating mycotic infections with autogenous or stock fungus vaccines. In all, 66 cases were studied with the following results—cured, 50, improved, 9, and unimproved, 7. Positive cultures were obtained in all but 13 of their cases so that their patients were carefully selected, but no mention was made about the all important point as to whether or not local treatment had been used together with their vaccine therapy.

Fonseca and Leao¹² produced a polyvalent vaccine which they claimed aroused antibody production and in turn stimulated a general immune mechanism. Their highly favorable results were substantiated in part by Motta.¹³

Eller and Kazanjian¹⁴ compared the results obtained by treating 50 patients with dermatomycol added to the regime and 50 patients that had been previously treated with similar local remedies but without the dermatomycol. They "gained the impression that the Fonseca vaccine did shorten the course of disease somewhat, but the results so far are by no means as striking and miraculous as reported in the literature."

Recently we¹⁵ studied another large series of cases of dermatophytosis, dermatophytosis with "ids," and tinea capitis. Sixty-five of these had been reported in detail. We used three different vaccines, all of which have been described in the literature. Our results were far from gratifying. Over 60 per cent of the cases were entirely uninfluenced by the treatment. About 9 per cent were apparently cured. It is our belief that the terms "cured" and "improved" in this disease are subject to question. This work convinced us that vaccine treatment of dermatophytosis is not yet practical and that further experiments are necessary.

Comment

It is immediately apparent from this review of the literature that a number of authors have reported high percentages of good results or "cures" with the various types of fungus extracts while a minority have found such preparations practically valueless. We question, in the first place, the advisability of using the term "cure" because only prolonged observation and repeated microscopic and cultural studies could determine this point. The difficulty of following up such cases is obvious.

We believe that only those experiments can be accepted where the authors actually proved that they were dealing with cases of dermatophytosis. "Mycotic-like" eruptions with a positive trichophytin test,¹ cases of probable "ids,"² and eczematous hand and foot eruptions clinically called dermatophytosis and dermatophytid (in the large majority of which it may be assumed that both the omnipresent *Monilia* and the almost om-

represent epidermophyton could have been found by careful mycologic investigation)² (but were not)* are not the carefully selected type of cases on which we believe such a study should be based.

Everyone is well aware of the fact that it is difficult to evaluate accurately the results of therapy in dermatophytosis, which even if left untreated runs a most capricious course of improvement, apparent cure, and relapse. Therefore, we believe it doubly difficult to judge the value of the biologic remedies where the authors used local measures in addition to the injections.

Conclusions drawn from a small series of cases even if carefully controlled otherwise are often fallacious. As we have mentioned, one of our cases improved materially after placebo injections of a normal saline solution. We cannot conclude from such an experience, however, that saline might be expected to be of value or that the result in the one case was anything but a coincidence.

Regardless of the type of vaccine or the type of case, we believe the number of patients entirely uninfluenced by treatment remains high and approximately the same—in our experience over 60 per cent—and the number of cured or improved cases relatively low and, in fact, much lower than our figures indicated. We found that the longer we followed our patients, the smaller grew the number of cases we were able to report as "cured" or "improved."

We do not feel that vaccine, trichophytin, or convalescent serum treatment of dermatophytosis should be discarded. We feel rather that we should take stock of these agents. We feel that the biologic methods of treatment still belong in the laboratory and should not yet be advocated for general use. Some good results in a small number of cases have been reported, but the reasons for the small percentage of good results regardless of the methods of biologic treatment should be investigated. Perhaps the soil on which the fungi grow is altered by factors which we have not taken into account and

which, if understood, might help us in controlling the disease. Certainly the general health of the patient is a factor. In one instance a long standing proved case of dermatophytosis was completely cleared up following a thyroidectomy. The patient has been observed for six to seven years since operation and the eruption has not recurred. Other such examples are not uncommon. Other methods of preparation of the vaccines and extracts must be considered too—and these methods tried out. The question of dosages must also be further studied. At the present time it is our belief that the usual local remedies, Whitfield's ointment, x-rays, boric acid ointment, wet dressings with boric acid, Burow's solution or potassium permanganate, et cetera, are still the most practical and useful agents at hand.

It is evident, therefore, that it should be agreed that the routine use of fungus extracts and vaccines by the dermatologist and general practitioner is not yet justified by the results obtained. The further work that must be done in this field should still be considered experimental only.

Discussion

Dr Samuel M Peck, *New York City*—The paper of Dr Traub's is very timely. It is gratifying to see one of the experienced investigators in this field take stock of the present status of the biologic methods of treating fungus infections. While the average case of dermatophytosis with and without "ids" is not a very difficult therapeutic problem, nearly every dermatologist sees enough cases, especially those with "ids," which are not only difficult to cure, but are very often almost impossible to control. The use of trichophytin of all types has proved very disappointing in my experience. Local and general reactions are often met with, especially focal reactions in the very lesions which we hope to control. When apparent "cures" are obtained, recurrences were fairly frequent. I agree with Dr Traub that one must differentiate between desensitization or suppression of a positive trichophytin test and a real immunity.

Very few of the investigators have pointed out that the type of infectious organism should be borne in mind in evaluating results of biologic methods of treatment. In the majority of instances in the trichophytin test we are dealing with a group reaction to fungi. In many cases a more specific trichophytin or vaccine might be necessary. It is for this reason that the polyvalent vaccine of Fonseca and Leao which contained many strains seems to be a more practical form of therapy. But due to its very contents of about 100 and more strains, there results a dilution of the individual organism or toxin. This in turn seems to me in the end to defeat the purpose of using such a polyvalent vaccine.

More critical choice of cases both as far as diagnosis and suitability, as far as the use of trichophytin for therapeutic purposes is concerned, is necessary. It seems to me that the treatment of fungus infections to be successful must be of the type which results in the eradication of foci of infection and thus prevents the formation of hypersensitivity on the one hand and disappearance of the "ids" on the other. We must admit that the present chemotherapeutic methods for treatment of fungus infections are most unsatisfactory.

Dr Marion B Sulzberger, *New York City*—We are all surely indebted to Drs Traub and Tolmach for this presentation. It should be pointed out that this paper is valuable in that it compiles the previous results of trichophytin therapy of dermatophytids at the hands of various investigators, adds a new series of cases, and again emphasizes the fact that this form of

treatment is not indicated as a routine measure. This last is precisely the conclusion Wise and I reached at the close of our first investigation of this particular problem. In this connection it is noteworthy that all previous workers since Plato-Neisser had employed trichophytin not in the treatment of the allergic eczematous secondary "ids" but in an entirely different manner, namely, as a stimulating measure to be used in the attempt to accelerate the cure of primary inflammatory foci of tinea infections. Wise and I, after more than two years' study completed in May, 1931, reported the following results of these first investigations on the possible value of trichophytin desensitization in the treatment of eczematous dermatophytids.

First, we noted the new and biologically important fact that repeated intracutaneous trichophytin injections almost regularly succeed in reducing the skin's "tuberculin-type" hypersensitivity to trichophytin. At approximately the same time and independently, Van Dyck, Kingsbury, Throne, and Myers succeeded in reducing the skin's hypersensitivity to trichophytin in a similar manner.* These results have been confirmed repeatedly and may now be regarded as an established proof of a general and basic immunologic phenomenon which may acquire significance in other fields, particularly, for example, in tuberculosis. However, Wise and I came to the conclusion that, "The method we have employed is by no means suitable for general treatment. At present we can recommend it only as an ultimate measure in severe and refractory cases occurring in co-operative patients. Nevertheless, the results do not discourage further attempts in this direction. Modifications of our methods may improve the results."†

Wise and I have discussed in some detail the possible causes for some of the many failures of trichophytin treatment, and indicated some of the directions in which improvements and modifications might be sought.‡

It is to be regretted that none of us, including Dr Traub and Dr Tolmach, has as yet been able to develop these hoped-for modifications which might improve the results.

I say this in spite of the fact that Dr Traub's and Dr Tolmach's results, even with the old method, seem somewhat better than those at our hands. (If I recall correctly they speak of 45 per cent improved and 10 per cent "cured.") I believe that this slight difference in results may be based upon the fact that our criteria for estab-

* New York State J. of Med., 31, 611 (1931).

† Quoted from an article submitted May 19, 1931, and appearing in the J. A. M. A., 99, 1,759 (1932).

‡ Year Book of Dermatology and Syphilology, pp. 23-26, 1937.

lishing the diagnosis of dermatophytid and for reaching conclusions as to therapeutic trichophylin-effect were stricter than those in the present series. It was for this reason that out of a large series of treated cases only 16 remained which could be considered satisfactory. For example, we reported only on cases of previous known unfavorable course and known refractoriness to all treatment for periods varying from one and one-half to fifteen years. This was done in order to exclude as far as possible the error due to possible spontaneous remissions. Second we chose only cases in which all other possible causes could be excluded as far as possible cases for example with negative patch tests to eczematous contact allergies, cases without remissions when away from external contact excitants (change of exposures constant occlusive gloves, etc.) cases without other demonstrable foci of infection (tonsils teeth, sinuses), and cases with proved foci of dermatophytosis. Only 16 cases of more than 100 studied eventually satisfied these rigid criteria and even these we called only probable *ids*. Moreover, we did not allow ourselves to fall into the all too common error of considering a case of probable "*id*" because the patient had a hypersensitivity to trichophylin or because *Trichophyton* fungi were demonstrable in a skin or nail lesion. These criteria are of relatively little value since it is established that in New York City at least 70 per cent of adults will have such skin reactions to trichophylin and will have such fungi present in skin or nails. Furthermore, we deliberately allowed our patients to continue with that form of local therapy which had previously been employed without beneficial effect. We believed this to be an essential to the correct evaluation of the possible beneficial effects of the additional trichophylin therapy. For it is only too well known that cases of dermatophytosis and *ids* may persist because of the irritating and other effects of local applications. So that if we had stopped the usual local applications we might have attributed to trichophylin effect a good result which was actually due to the cessation of irritating treatment. And in spite of these and similar differences in details of selection and of criteria for cure, etc. the results in the ultra carefully selected and controlled series of Wise and myself were so close to those today that our conclusions were almost verbatim those of the present authors.

In closing I should like to thank Dr. Traub and Dr. Tolmach for devoting their time and energy to further statistical studies with this method and particularly for once again stressing what I think is an extremely important and urgently necessary practical conclusion namely

trichophylin therapy of dermatophytosis and dermatophytids is not at present suitable as a routine or general therapeutic measure. It seems to me that this method stands today precisely where it was when introduced in 1931 that is as Wise and I stated. The method we have employed seems to meet with success in the treatment of a comparatively small number of cases. However these permit the hope that modifications may improve the results.

Dr. Herman Goodman, New York City—Sometime in 1917 I saw a patient in consultation whose lesion on the forehead I diagnosed as tertiary syphilis (gumma). My colleague in this case insisted that the lesion was due to ringworm. A culture was made and organisms recovered. A Wassermann test was made and reported four plus. The lesions disappeared completely under the influence of antisyphilitic intravenous treatment without external applications of any kind.*

A group of silk handlers who were diagnosed by specialists in skin diseases for the Compensation Bureau of the State Insurance Fund some years ago as having ringworm of the hands were refused industrial compensation. On mature study and after visits to the silk throwing mills, it was determined that the lesions of the hands, which had been diagnosed as ringworm were due to some element in the solutions used in the factory. This group of patients has since been reported.†

I wish to call attention of the members of this section to the report made by Dr. Irving Marks and me some years ago.

Groups of patients with ringworm clinically and bacteriologically were given intradermal tests with varied combinations of trichophylin vaccines of streptococci, staphylococci, colon, and tuberculin. It was found that some patients reacted to all of these intradermal injections. Other patients responded to none. At the time of reporting these findings there was much discussion as to their validity. I have not found any report in recent literature which contradicts these findings.‡

The next observation concerned 75 women who were completely free of evidence of tinea infection. They were selected because they were not exposed to any obvious industrial or household irritant. This group of women was diagnosed clinically as showing hand lesions which were indistinguishable from those occurring in persons

* Gumma of the Forehead with Ringworm. J.A.M.A. 79: 200 (1922).

‡ Reactions to Trichophylin Compared with Reactions to Other Bacterial Products, Arch. Derm. 31: 818 (1933).

with definite ringworm infection. This group of patients indicates that clinical diagnosis is not sufficient to classify patients in a group of trichophytid.*

My last observation concerns a chemist who was treated by many physicians with topical applications and x-ray to no avail. Although he gave no clinical, microscopic, or cultural evidence of ringworm, this patient was completely cured by the administration of four doses of trichophytin intradermally at intervals of one week, and has remained well for about seven years.

These observations indicate the difficulties which beset the study of ringworm and ringworm reactions.

Dr Paul Gross, *New York City*—I was very much impressed with Drs Traub and Tolmach's paper, and particularly by the unavoidable conclusions about the doubtful value of trichophytin in the treatment of dermatophytosis. It is true, as Dr Lewis said, that the results with trichophytin treatment were good prior to 1930, but this is due to the fact that it was used for those conditions for which it had been devised, namely, deep trichophytosis of the bearded region and kerion celsi. Before we go on to improve our methods with trichophytin treatment, we should first consider the fundamental reasons why fungus infections of the Trichophyton group, which give rise to deep tissue reactions and even systemic symptoms, respond to trichophytin treatment, while eczematoid ringworm (to use Dr Fordyce's name) does not. It seems to me that we have a good parallel in gonorrhea where the cases complicated with acute prostatitis, epididymitis, etc., are an excellent field for vaccine therapy, while the simple urethritis does not respond to the treatment. The desensitizing effect of trichophytin on the trichophytin reaction itself, as pointed out by Dr Sulzberger, is an encouraging fact, but only shows how complicating the problem is even without the assumption of the well-known multiple sensitization in dermatophytosis. That spontaneous immunization can take place is best demonstrated by those cases of dermatophytosis who show extensive dermatophytid reactions with systemic symptoms. I would mention particularly cases with severe involvement of the feet, and lichen trichophytic-like eruption on the body, and secondly, some cases who develop erysipelas-like dermatophytid without recurrences. Such cases at a certain point make a prompt recovery, and can be observed for years without showing any signs of dermatophytosis. Whether experience with

such cases can give us any hope that a real immunity can be produced by some improved technic of trichophytin treatment is at least very doubtful, especially after one has listened to this excellent paper.

Dr Eugene F Traub, *New York City*—The interest displayed, if I may judge by the number of men who discussed the subject, shows that this is a matter of vital interest to all. I am particularly grateful and thankful that there seems to be quite a general agreement with the result as presented in our study.

To answer several of the "discussers," I might say that we realize that the finding of fungi does not necessarily prove the eruption to be a dermatophytosis. The eruption might be a syphilitic one and the fungi might simply be a casual superimposed finding of no significance, on the other hand, the failure to find fungi or the failure to culture fungi, leaves anyone doing experimental work with only a clinical guess in place of a diagnosis. The statistical studies of the vast experimental work done in our various series of cases, to which Dr Sulzberger has repeatedly referred, is no doubt staggering to him when he compares it to his report of 16 cases which he believes were tinea, although he had no proof of the point. As I stressed in the beginning of our presentation, that while the finding of the fungi is most essential, the eruption must also conform to one of the usual types regularly recognized as a manifestation of dermatophytosis. Dr C. M. Williams, who was one of the most careful and painstaking of observers, refused to accept a diagnosis of dermatophytosis in which the presence of the organism could not be proved.

The question concerning the advisability of studying a large series of cases perhaps can best be answered by telling you an experience of Dr Williams. A number of years ago he treated a series of 5 or 6 patients with juvenile flat warts with protoiodide mercury pills. In each case the eruption promptly disappeared. He was inclined to report his experience but thought it best to get a larger series of cases before doing so. Over the next few years he failed to find another case in which he had the slightest response to this type of therapy. Needless to say his report never went to press. No doubt every one else has had a similar experience. Great inaccuracies and misleading reports thus frequently get into the literature where the results of therapeutic experiences are reported on a small series of cases, regardless of how well these cases may have been studied.

The point made about continuing local treatment on cases in which the results of specific

* Eczema of the Hands, *Amer Med* p 186 (1932)

vaccine therapy is being evaluated is obviously not well taken. We sincerely hope that the local treatment used by the various authors as suggested by Dr Sulzberger was not intended by them to irritate the process but rather was given

with an honest intention to promote improvement. Such being the case, it is naturally utterly impossible to judge the relative value of either the local or the internal treatment when both are employed simultaneously

PRIZE ESSAYS

of the Medical Society of the State of New York

The Merrit H Cash Prize will be open for competition at the next Annual Meeting of the Medical Society of the State of New York to be held April 24, 1939, in Syracuse, New York

This prize of ONE HUNDRED DOLLARS will be given to the author of the best original essay on some medical or surgical subject.

Competition is limited to the Members of the Medical Society of the State of New York, who at the time of the competition are residents of New York State.

The following conditions must be observed
Essays shall be typewritten or printed and the only means of identification of the author shall be a motto or other device. The essay shall be accompanied by a sealed envelope having on the outside the same motto or device and containing the name and address of the writer

If the Committee considers that no essay or contribution is worthy of the prize, it will not be awarded.

All essays must be presented not later than April 1, 1939, and sent to the Chairman of the Committee on Prize Essays of the Medical Society of the State of New York, 2 East 103rd Street, New York City

FRANK B CROSS, M.D., Chairman
Committee on Prize Essays

"PAY YOUR DOCTOR WEEK" IN LOS ANGELES

Recognizing the fairly widespread tendency on the part of the public to regard physicians bills as obligations that can wait indefinitely or at least until after all other bills have been paid California Bank Los Angeles during the week of Oct. 31-Nov 5 inaugurated Pay Your Doctor Week, with 3-column 6-inch ads in local daily newspapers and reprints of the ad in approximately 35 000 month-end checking account statements calling attention to the dedicated week and to the bank's personal loan plan for paying physicians and other bills

UNCLE SAM GROWING OLD AND FOOLISH?

By 1900 the amount of mental disease in the nation will be double what it now is if it progresses at the same rate as at the present Harold F Dorn, statistician of the United States Public Health Service predicts in a survey of the situation published by the federal health service.

Increasing age of the population, and not the stress and strain of modern life is the factor that will double the amount of mental disease in the nation, according to the findings of Mr Dorn

A STUDY OF INFANT WELFARE IN ST. LAWRENCE COUNTY IN 1935

STANLEY W. SAYER, M.D., Gouverneur, New York

IN JULY, 1934, Dr. Thomas Parran, then Commissioner of Health of New York State, addressed letters to the administrative and health authorities as well as to the medical societies of the ten cities and the ten counties which had had consistently higher infant mortality rates than for the state at large, with the purpose of encouraging concentrated efforts to reduce these rates. As a result of this stimulation, the St. Lawrence Medical Society co-operated with the Division of Maternity, Infancy, and Child Hygiene of the New York State Department of Health in a detailed study of all the live births that occurred in the county in 1935. Assistance for this study has also been given by the T.E.R.A. which furnished the services of a physician for four months.

Method

The study was conducted by means of personal interviews. All the live births between January 1 and December 31, 1935, were followed for a period of twelve months or such part of it as the infant lived. First, a staff physician interviewed the attending physician and recorded the information concerning prenatal care and delivery, at the same time securing the attending physician's permission for home visits by public health nurses. These nurses made periodic visits to the home and recorded the general care given to the infant, the history of the mother's previous pregnancies, and the economic status of the family. They assisted the mothers in carrying out the physician's instructions and attempted to be of service in the promotion of better care for the infants.

Limitations

The method outlined above, that is, that of following all the births in a given locality for a definite period of time and securing pertinent information for the surviving infants as well as for those who died, is without a doubt the best available method which might throw light on the complex problem of the variations of infant mortality. However, in order to obtain maximum results it is essential to have complete co-operation of all participants in the study. It is of utmost importance that the interval between the birth and the first interview with the physician be as short as possible so that in case the physician does not keep a written record, the case will be fresh in his mind.

It is unfortunate that due to certain administrative complications (arising mostly from the difficulty of securing the services of the T.E.R.A. physician) the study did not get under way until the middle of July so that in many cases the information concerning the births that occurred six or seven months previously was given by memory. Furthermore, the schedule in many instances was not as complete and as clearly worded as might be desired. Moreover, most of the factors which might affect infant mortality are very strongly intercorrelated, so that in order to isolate any required factor and study its effect independently of the other factors a much larger number of births than the one on which this study is based is required. The results of the study must, therefore, be considered merely as indications and suggestions. They must be substantiated by more careful study of a much greater number of births before real significance can be attached to them.

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, May 12, 1938

General Facts Concerning St. Lawrence County

St. Lawrence County is located in the northern part of New York State on the Canadian border. It is predominantly rural. It covers an area of 2,701 square miles and its population, estimated as of July 1, 1935, was 89,549. This gives an average density of 33 persons per square mile compared with an average density of 120 persons per square mile for upstate New York. There is one city in the county (Ogdensburg) with an estimated population of 15,277 and four villages of from 2,500 to 10,000 population.

The principal occupation is agriculture. 32.7 per cent of the male population over 10 years of age in the county being engaged in it compared with 12.5 per cent in upstate New York (1930 census).

Persons of Canadian birth or parentage formed 8.2 per cent of the county's population (1930 census).

The birth rate in the county was considerably higher than in the upstate area. The average rate for the five year period 1931-1935 was 19.3 as against the average rate of 15.0 in the state. The average death rate for the same period was 14.1 in the county and 12.2 in upstate New York. The stillbirth and infant mortality rates were consistently and considerably higher in the county than in the upstate area. The excess in the average rate for the five year period 1931-1935 was over 30 per cent. The county compares most unfavorably with the state in deaths of infants aged one month to one year, the excess in the average rate for the five-year period being 49 per cent. This excess was present for practically all causes. The rate was especially high for the group of gastrointestinal diseases (10.8) which was more than two and one-half times the rate for the upstate area (4.0).

General Results

Between January 1 and December 31, 1935, there occurred in St. Lawrence County 1,647 live births. For 82 of these births no information could be secured either because the mother moved out of

Chart 1—Annual infant mortality rates per 1,000 live births, St. Lawrence County 1930-1936

the county (65) or because she could not be located for other reasons (17). This study is concerned, therefore, with the remaining 1,565 infants. Of these, 91 died before reaching their first birthday. The true* infant mortality rate for the county was, therefore, 58.1 per 1,000 live births.

Infant mortality in the county dropped considerably during the year of study as is shown in the following table:

| YEAR | INFANT MORTALITY RATE |
|------|-----------------------|
| 1930 | 82.0 |
| 1931 | 87.9 |
| 1932 | 67.3 |
| 1933 | 77.6 |
| 1934 | 69.3 |
| 1935 | 50.0† |
| 1936 | 66.3 |
| 1937 | 69.8 |

† The ordinary rather than the true rate is used in the table since the rates for the other years are on the same basis.

This drop in the rate during the year of the study, in a sense, complicates the

* The true rate differs from that given ordinarily for infant mortality in that it is obtained from the deaths occurring among the infants born in a certain year irrespective of the calendar year in which they died, while the ordinary rate is obtained by dividing the number of deaths occurring in a given year by the number of live births in the same year. The ordinary rate in St. Lawrence County for 1935 was 50.0.

PRIMARY AND CONTRIBUTORY CAUSES OF INFANT DEATHS, ST LAWRENCE COUNTY—1935

| PRIMARY CAUSE OF DEATHS | TOTAL | CONTRIBUTORY CAUSE OF DEATHS | | | | | | Total |
|---------------------------|-------|------------------------------|----------------------|--------------------------|---------------------------|----------------------------|----------------|-------|
| | | Premature Birth | Respiratory Diseases | Congenital Malformations | Diseases of Early Infancy | Gastro-intestinal Diseases | Other Diseases | |
| Total | 91 | 5 | 4 | 4 | 7 | | 11 | 31 |
| Premature birth | 27 | | | 2 | 1 | | 1 | 4 |
| Respiratory diseases | 17 | | 4 | | | | 7 | 11 |
| Congenital malformations | 15 | 2 | | 2 | 2 | | | 6 |
| Diseases of early infancy | 13 | 1 | | | | | 1 | 2 |
| Gastrointestinal diseases | 9 | | | | 2 | | 2 | 4 |
| Other diseases | 10 | 2 | | | 2 | | | 4 |

conclusions that may be drawn from such a study. However, this in itself is an important result especially since it is found to occur also in other studies now carried on in various parts of the state.

Causes of Death

The primary and contributory causes of death as given on the death certificates are shown in the table above.

Premature birth was given as a primary cause of death in 27 or 30 per cent of the deaths. There were 11 other prematurely born infants who died. In 5 of these, premature birth was given as a contributory cause of death and in the remaining 6, prematurity was not recorded on the death certificate.

It is of interest to note that the death rate from gastrointestinal disease (5.8) was much lower in the year of the study than in previous years and was not higher to a considerable degree than the rate in the state at large.

On only 31 of the 91 death certificates was a secondary cause given. The distribution of these by primary cause is shown in the above table. The group of respiratory diseases had the largest proportion of secondary causes, on 11 of the 17 certificates, a second cause was given. The group of diseases of early infancy was the most common contributory cause accounting for 7 of the 31 secondary causes.

The table on the opposite page gives the distribution of the 91 deaths by age at death and primary cause of death.

More than one-half of the deaths occurred while the infant was less than one month old and more than one-fourth of them occurred in less than twenty-four hours after delivery. Practically all these

Chart 2—Percentage distribution of infant deaths by primary cause and by age at death, Infant Welfare Study, St. Lawrence County—1935

deaths were recorded as due to premature birth, malformations, and diseases of early infancy. A disproportionate number of deaths occurred when the infant was in its sixth month (a total of 9 deaths, while in the total period of 6 to 11 months, there were only 10 deaths). Six of these infants died from a respiratory disease and one additional had a respiratory disease as a contributory cause. Most of these deaths were due to pneumonia. A checkup of the certificates showed that they were not especially concentrated either in locality or in month of death.

The largest number of deaths occurred in February (14), the lowest number of deaths took place in October (2). Deaths

INFANT MORTALITY BY AGE AT DEATH AND BY PRIMARY CAUSE OF DEATH, ST LAWRENCE COUNTY—1935

| AGE AT DEATH | TOTAL | PERCENTAGE OF TOTAL DEATHS | PRIMARY CAUSE OF DEATH | | | | | |
|---------------------|-------|----------------------------------|------------------------|-------------------------|--------------------|------------------|-----------------------------------|-------------------|
| | | | Premature Birth | Respiratory Diseases | Malfor- mations | Early Infancy | Gastro- intestinal Diseases | Other Diseases |
| Under 1 day | 24 | 20.4 | 10 | | 3 | 6 | | |
| 1 day to 1 week | 13 | 14.3 | 5 | 1 | 4 | 3 | | |
| 1 week to 1 month | 11 | 12.1 | 3 | | 4 | 2 | 1 | 1 |
| Total under 1 month | 48 | 52.7 | 24 | 1 | 11 | 10 | 1 | 1 |
| 1 month | 8 | 8.8 | 1 | 1 | 1 | | 1 | 1 |
| 2 months | 7 | 7.7 | 1 | 1 | 1 | 2 | 3 | 1 |
| 3 months | 5 | 5.5 | | | 1 | | | 3 |
| 4 months | 4 | 4.4 | | 1 | 1 | | 1 | 1 |
| 5 months | 9 | 9.9 | | 6 | | | 2 | 1 |
| 6 months and over | 10 | 11.0 | | 6 | | 1 | 1 | 2 |
| Total | 91 | 100.0 | 27 | 17 | 15 | 13 | 9 | 10 |

from respiratory diseases were concentrated in the winter and spring while those from gastrointestinal diseases were more frequent in the summer months. Infants born in December had the highest death rate (100.8), those born in May, the lowest (33.6).

Place of Birth

There was no significant difference in the infant mortality rate for the rural and urban residents. However, when the rural births were classified according to whether they were easily accessible (type of roads and distance from nearest physician) or inaccessible, the rate for the latter (85.9) was higher than that for the easily accessible group (47.1).

Two out of every three births in St. Lawrence County occurred at home while only 39 per cent of the births in upstate New York were home births. The infant mortality rates for home and hospital births do not differ significantly. However, when the hospital births were classified by residence of mother, whether it was in the same or in a different town than the hospital, the rate for the latter was significantly high.

INFANT MORTALITY FOR HOSPITAL BIRTHS BY RESIDENCE OF MOTHER

| RESIDENCE OF MOTHER | BIRTHS | DEATHS | RATE* |
|------------------------------|--------|--------|-------|
| Same town as hospital | 316 | 12 | 38 |
| Different town than hospital | 194 | 17 | 88 |

* Per 1,000 live births.

This cannot be explained entirely by the fact that the more difficult deliveries are

hospitalized. Since the excess of the deaths occur mostly from respiratory, gastrointestinal, and other causes which are presumably less affected by difficult delivery than the group of premature birth malformations, and diseases of early infancy.

The figures, however, are too small to allow valid conclusions and a study of this point for all the births in the state is being done now by the Division of Maternity, Infancy, and Child Hygiene of the State Department of Health.

Age of Mother, Order of Birth, and Racial Stock

The welfare of infants is known to depend to a considerable degree on the order of birth, the size of the family, and age of the mother. These factors are strongly intercorrelated and because of the small number of births on which this study is based, only a crude analysis measuring their combined effect is possible.

The women of childbearing age in St. Lawrence County are on the whole younger than in upstate New York. A comparison of the age distribution of the mothers of the 1935 infants in St. Lawrence County and upstate New York shows that the women in St. Lawrence County began bearing children on an average sooner and continue to bear them for a longer period than the women in upstate New York with result that the size of the family must be much larger in St. Lawrence County. A rough estimate shows that the average number of children in a completed fruitful family in St. Lawrence County is 3.9 while in the up

Chart 3 —Infant mortality rates per 1,000 live births by age of mother, Infant Welfare Study, St Lawrence County—1935

Chart 4 —Infant mortality rates per 1,000 live births by order of birth, Infant Welfare Study, St Lawrence County—1935

state area it is only 2.8. The following tables showed infant mortality rates by age of mother and order of birth.

It will be noticed that the rate starts high for first births as well as for young mothers. There was a drop to a minimum for second births as well as for mothers aged 20 to 24. From then there was a continuous rise in mortality with order of birth as well as with age of

mother. This is in agreement with other studies on this point.

The presence in St Lawrence County of a considerable number of French-Canadians presented the possibility of determining whether there is a considerable variation of infant mortality by racial stock. The results show that although there is a very slight increase in the rate for the infants of the French-Canadian stock, it is not of a significant magnitude.

INFANT MORTALITY BY AGE OF MOTHER, ST LAWRENCE COUNTY—1935

| AGE OF MOTHER | BIRTHS | DEATHS | RATE* |
|----------------|--------|--------|-------|
| Under 20 years | 175 | 14 | 80.0 |
| 20-24 years | 471 | 21 | 44.6 |
| 25-29 years | 407 | 24 | 59.0 |
| 30-34 years | 276 | 14 | 50.7 |
| 35-39 years | 161 | 11 | 68.3 |

† Per 1,000 live births

History of Previous Pregnancies

The history of mothers' previous pregnancies had a great effect on the chances of survival of the infants born in 1935 as is shown in the following table.

INFANT MORTALITY RATES BY HISTORY OF PREVIOUS PREGNANCIES

| | PREVIOUS STILL-BIRTH | PREVIOUS MIS-CARRIAGES | PREVIOUS INFANT DEATHS | COMP IN PREVIOUS PREGNANCIES |
|--------------|----------------------|------------------------|------------------------|------------------------------|
| None | 44.4 | 46.7 | 44.4 | 41.4 |
| At least one | 101.4 | 145.5 | 72.9 | 69.0 |

Infants born to mothers who have had previously at least one stillbirth or a mis-

INFANT MORTALITY BY MONTH OF MOTHER'S FIRST VISIT TO PHYSICIAN FOR PRENATAL CARE ST. LAWRENCE COUNTY—1935

| MONTH OF FIRST VISIT | BIRTHS | PERCENTAGE OF TOTAL | DEATHS | RATES* |
|------------------------|--------|---------------------|--------|--------|
| No visits | 274 | 17.5 | 23 | 83.9 |
| 1st month of pregnancy | 34 | 1.5 | 1 | |
| 2nd month of pregnancy | 120 | 7.7 | 9 | 75.0 |
| 3rd month of pregnancy | 190 | 12.1 | 9 | 47.4 |
| 4th month of pregnancy | 162 | 10.4 | 12 | 74.1 |

| 8th month of pregnancy | 162 | 10.4 | 3 | 18.5 |
| 9th month of pregnancy | 40 | 2.6 | | |

* Per 1,000 live births.

carnage or a child who died in infancy, or, if they had some complication in a previous pregnancy, had a considerably higher mortality than the infants of mothers who had had no such complications.

The mothers of the 1,565 infants had 4,041 previous pregnancies. The number of stillbirths was 47.8 per 1,000 total births and 68.5 per 1,000 live births died in infancy.

Of the 3,957 previous deliveries which terminated either in a live or stillbirth, 78 per cent were home deliveries, for 12 per cent of them instruments were used, and for 55 per cent of them the mother stated that she had had some prenatal care be-

ginning at least with the seventh month of pregnancy.

The advantage of prenatal care may be seen from the fact that the infants of the mothers who had had prenatal care had a stillbirth rate of 34.5 and an infant mortality rate of 53.3 as against a stillbirth rate of 64.0 and an infant mortality rate of 82.0 for infants of mothers who had had no prenatal care.

Prenatal Care

The table above shows the distribution of births and infant deaths by the month of pregnancy in which the mother first visited her physician.

Chart 5—Infant mortality rates per 1,000 live births by history of previous pregnancies, Infant Welfare Study St. Lawrence County—1935

Chart 6—Percentage distribution of births by month of mother's first visit to physician for prenatal care Infant Welfare Study St. Lawrence County—1935.

Chart 7—Infant mortality rates per 1,000 live births by results of physical examination, Infant Welfare Study, St. Lawrence Co.

Nearly 18 per cent of the mothers did not go to a physician before delivery. An additional 25 per cent did not see a physician before the seventh month of pregnancy. The 274 infants whose mothers did not visit a physician during pregnancy had a mortality rate of 83.9 compared with the rate of 52.7 for all the other infants. The comparatively low rate of infants whose mothers did not visit a physician until the late months of pregnancy is due to the fact that they consist of full term infants only, the premature infants having been eliminated in the previous months.

The type of care that the physicians in St. Lawrence County gave to the 1,291 expectant mothers who visited them during pregnancy can be seen in the following: in 92 per cent of the cases, urinalysis was stated to have been done, 89 per cent was stated to have had their blood pressure taken, 64 per cent were known to have had pelvic measurements taken, however, only 21 per cent of primiparae did not have these measurements taken, and only 8 per cent were stated to have had a Wassermann test.

The proportion of abnormalities observed in those stated to have had ex-

aminations made were as follows: Wassermann, 16.3 per cent, blood pressure, 12.6 per cent, urinalysis, 8.3 per cent, pelvis, 8.3 per cent. The difference in infant mortality in the normal and abnormal groups as shown in the following table is striking, although they are based in some instances on a rather small number of births.

INFANT MORTALITY RATES BY RESULTS OF PHYSICAL EXAMINATION

| | URINALYSIS | BLOOD PRESSURE | WASSERMANN | PELVIS |
|----------|------------|----------------|------------|--------|
| Normal | 48.6 | 46.6 | 69.0 | 40.8 |
| Abnormal | 90.9 | 89.0 | 117.6 | 144.9 |

Complications of Last Pregnancy

Of the 1,315 mothers for whom this item was recorded, 271 or 21 per cent had complications during their last pregnancy. The total number of complications reported was 349 of which 194 were puerperal in nature and 151 nonpuerperal. The most frequent puerperal complication was mild toxemia and edema (80) followed by hemorrhage (28). In the nonpuerperal the most common complication was chronic organic conditions (43), followed by mental and nervous conditions (24).

The mortality of infants whose mothers had complications during pregnancy was four times as high as that of infants whose mothers had no complications, the rates being 136.5 and 33.5, respectively. The excess was mainly due to prematurity as seen from the table on the opposite page.

Labor and Delivery

In 80 per cent of the births, labor and delivery were spontaneous. In 16 per cent of them forceps were used. There were 13 deliveries by caesarean operation, 12 were version extraction, and 35 were breech presentations.

Mortality for version was highest. Four of the 12 infants thus delivered died. High forceps came next with 3 deaths out of 12. Two of the 13 infants delivered by caesarean operation died and 4 of the 35 breech presentations.

CAUSES OF INFANT DEATHS BY COMPLICATIONS DURING PREGNANCY

| | TOTAL | PER MATURE | EARLY INFANCY | MALFOR- MATIONS | RESPIRA- TORY | GASTRO- INTESTINAL | OTHER |
|-----------------------------|-------|---------------|------------------|--------------------|------------------|-----------------------|-------|
| Mother had complications | 37 | 10 | 7 | 3 | 6 | 2 | 3 |
| Mother had no complications | 36 | 5 | 7 | 11 | 8 | 4 | 4 |

On only 16 hirths was it stated that labor was induced. Of these, 2 infants died. It is of interest to note that 13 of these deliveries were operative.

The average duration of labor was 8.8 hours.

The average weight at birth was 7 lbs. There were 67 infants weighing less than 5 lbs. of whom 30 died. The lowest infant mortality was recorded for infants weighing 8 lbs. (31.0).

The following table shows the distribution of births and deaths resulting from them by period of gestation.

INFANT MORTALITY BY PERIOD OF GESTATION ST LAWRENCE COUNTY—1935

| PERIOD OF GESTATION | BIRTHS | DEATHS | RATE* |
|------------------------|--------|--------|-------|
| Full term | 1,406 | 53 | 35.4 |
| Premature (total) | 69 | 38 | 550.7 |
| 6 months or less | 18 | 14 | 777.8 |
| 7 months | 27 | 21 | 777.8 |
| 8 months | 24 | 3 | 125.0 |

* Per 1,000 live births.

There were 69 infants born prematurely of whom 38 died. The infant mortality for premature infants was 550.7 as compared with a mortality of 35.4 for full-term infants. Thus, if all infants were carried to full term, the total infant mortality would be reduced by over 40 per cent.

For only a small number of births was the condition at birth given as 'fair' or 'poor'. Of the 41 hirths whose condition was given as 'fair,' 10 died and 33 of the 50 infants born in 'poor' condition eventually died. A larger proportion of these infants than of the infants born in good condition were first births. The respective proportions of first births were 37 per cent for the 'fair' group, 34 per cent for the 'poor' group, and 26 per cent for the total. Similarly, a larger proportion of the 'fair' and 'poor' groups were prematurely born. The respective percentages were 44 for 'fair,' 52 for 'poor,' and 4 for total. Also the

proportion of mothers with abnormal pelvis was much higher for the 'poor' group than for total. The respective percentages were 33 and 9.

For 175, or 11 per cent of the infants some unusual condition at birth was noted on the schedule. The number of such conditions was 242 as shown in the following table.

UNUSUAL CONDITIONS OF CHILD AT BIRTH ST LAWRENCE COUNTY—1935

| UNUSUAL CONDITIONS | BIRTHS | DEATHS |
|--------------------------------|--------|--------|
| Cyanosis | 54 | 27 |
| Premature | 69 | 38 |
| Birth injury | 20 | 4 |
| Multiple birth | 27 | 5 |
| Artificial respiration | 10 | 1 |
| Jaundice | 10 | 3 |
| Hernia | 21 | 2 |
| Congenital heart malformations | 4 | 3 |
| Other congenital malformations | 11 | 0 |
| Monstrosity | 2 | 2 |
| Other unusual conditions | 14 | 4 |

The mortality of these infants was much higher than for the infants presenting no unusual condition at birth. The respective rates were 337.1 and 22.9. One half of the cyanotic infants and over one-half of the premature infants died in infancy.

Care of Infant

The information required on the schedule concerning the care of the infant in his first year of life consisted of the following items: when seen by physician, how many months was the infant breast fed, when did artificial feeding begin, reason for weaning, kind of milk used, the use of cod liver oil, orange or tomato juices, cereals, and vegetables, number of visits by the public health nurse, gain in weight, feeding supervision by physician, bowel habits and the use of laxatives.

Since there was no question on the schedule concerning illnesses, and since the question with respect to physician's visits and supervision of feeding were not definite enough, it is impossible to determine whether these visits were for the purpose of check up or due to illnesses of

Chart 8—Percentage distribution of infants by type of feeding and month of life, Infant Welfare Study, St. Lawrence County—1935

the infant. This seems to explain the reason why the rate for infants whose feeding was supervised by a physician (43.1) was higher than the rate for the group of infants whose feeding was not supervised (19.3). Similarly, little significance can be placed on the answers to the questions of gain in weight, bowel habits, and the use of laxatives either because the question was not stated conclusively enough or because of the incomplete answers.

Type of Feeding—A number of studies have shown that breast-fed infants have tremendous advantages in terms of their infant mortality rate and the incidence of various diseases over those artificially fed. It is probably true that breast feeding is very advantageous for the infant. However, the differences in the rates are not of such high order of magnitude as most of the studies indicate. The reason is that in almost all of the studies the group of the artificially fed and the group of the breast-fed infants are not strictly comparable. The group of artificially fed infants contains a number who are artificially fed because they are unable to nurse due to a weakening condition at

birth (mostly premature). The mortality in this group is, of course, very high. Moreover, a number of them are weaned because they are doing poorly on breast feeding. These two reasons tend to raise the mortality of the artificially fed group. A careful study of this question can be made only when all the pertinent factors are taken account of. Thus it is impossible to do with the small number of births on which this study is based. It is hoped when the results of the studies now carried on throughout the state are accumulated, a more thorough study of this point will be made.

The following table gives the percentage distribution of the infants by the type of feeding they received in the various months of their lives.

PERCENTAGE DISTRIBUTION OF INFANTS BY TYPE OF FEEDING AND MONTH OF LIFE

| MONTH OF LIFE | EXCLUSIVELY BREAST FED DURING SPECIFIED MONTH | PARTLY BREAST FED DURING SPECIFIED MONTH | ARTIFICIALLY FED DURING SPECIFIED MONTH |
|---------------|---|--|---|
| 1st | 73.5 | 11.0 | 15.5 |
| 2nd | 61.2 | 17.7 | 21.1 |
| 3rd | 53.2 | 20.7 | 26.1 |
| 4th | 47.2 | 22.4 | 30.4 |
| 5th | 42.7 | 24.3 | 33.0 |
| 6th | 35.6 | 27.1 | 37.3 |
| 7th | 28.8 | 29.0 | 42.2 |
| 8th | 26.1 | 30.8 | 43.1 |
| 9th | 20.1 | 31.0 | 48.9 |
| 10th and over | 7.8 | 24.9 | 67.3 |

Three out of every four infants were breast fed for the first month of their lives. The proportion of exclusively breast-fed infants dropped with the age of infants so that when they were 6 months old only a little over a third of them and at age 10 to 12 months only 8 per cent of them were fed only breast milk. The group that was only partly breast fed formed an essentially constant proportion up to the sixth month of life and rose gradually thereafter. The percentage of the artificially fed group rose sharply at the second month from 16 per cent to 31 per cent and from then on rose continuously. At the age of 6 months a little over one-half of the infants were artificially fed and toward the end of the first year of life, the proportion rose to over two-thirds.

Out of the total number of months lived

| 9th | 206 | | | 374 | | | 905 | | |
| 10th and over | 116 | 1 | 8.7 | 307 | | | 993 | 4 | 4.0 |

by the infants a little over a third were exclusively breast fed, about one-sixth were partly breast fed, and one-half of them were exclusively artificially fed.

The table above shows the infant mortality rates for the above three groups. It shows for each month of life the number of infants who took the specified feeding during that month and the deaths that resulted among them.

The rate for the artificially fed group during the first month of life is considerably higher than for the breast-fed group. The figures are not large enough for comparison of the other monthly rates. It is in the accumulated experience of the various months that the advantage of breast feeding appears. In the period from the second to the ninth month, inclusive, there were 4,719 months of exclusive breast feeding, 1,463 months of mixed feeding, and 5,736 months of exclusively artificial feeding. There were six deaths in the first group, three in the second, and twenty six in the third. The corresponding rates per 1,000 months were 1.27, 2.10, and 4.53. Thus, roughly, the rate for the artificially fed group was 3.6 times that of the breast fed group.

Only a little over one-fourth of the infants used pasteurized milk while nearly one-half of them drank raw milk. The death rate for the latter was slightly but not significantly higher than for the former.

A negligible proportion of the infants received cod liver oil or fruit juices early enough. Only 27 per cent of the infants had these foods for six or more months of the first 12 months of their lives. Over one third of the infants had no cod liver oil at all. Another third had a very inadequate amount of it.

Economic Factors

The questions on the schedule concerning the economic condition of the family consisted of the following: a general statement as to the apparent economic status rated by a nurse as "good," "fair," and "poor"; the presence of a bathroom in the house, crowding, cleanliness, and ventilation, the kind of water supply, the occupation and employment status of father and relief status of the family. Most of the questions requested the opinion of the nurse and as such are subject to variation in personal judgment. On the whole the study confirms the results of other surveys: infant mortality rises with poorer economic conditions.

The following table gives the distribution of infants and the infant mortality rates by economic status of the family for full term and premature infants.

Those in "good" economic condition form 21 per cent of the total, 42 per cent were in the "fair" group, and 35 per cent were in poor economic status. The infant mortality rate was lowest for the group

INFANT MORTALITY BY ECONOMIC STATUS FOR FULL-TERM AND PREMATURE INFANTS

| ECONOMIC STATUS | BIRTHS | PERCENTAGE OF TOTAL BIRTHS | INFANT MORTALITY RATES | | |
|-----------------|--------|----------------------------|------------------------|-------------------|-------------------|
| | | | Total | Full Term Infants | Premature Infants |
| Good | 320 | 20.8 | 33.8 | 12.3 | 21.5 |
| Fair | 661 | 43.8 | 43.9 | 30.3 | 13.5 |
| Poor | 581 | 38.2 | 78.1 | 47.2 | 30.9 |
| Not stated | 27 | 1.7 | | | |

Chart 9—Infant mortality per 1,000 live births by economic status, Infant Welfare Study, St. Lawrence County—1935

in "good" economic condition. The rate in the "fair" group was 40 per cent higher than that of the "good" group. Infants born in families of "poor" economic condition suffered a risk of death which was over two times as high as those born in "good" economic condition.

The variations of infant mortality with economic status were due almost entirely to full-term infants. In fact, after the "fair" and "poor" groups are combined for the premature infants, the rate for this total group is the same as that for the group in "good" economic condition, while the mortality for combined group of "fair" and "poor" among the full-term infants was three times as high as that in the "good" economic condition.

This is not surprising since the premature infants die at an early age and are, therefore, not subject to the environment of the family and to the discrepancies in care to the same degree as the full-term infants are.

The same remarks apply for the other factors which are closely associated with economic condition, such as presence of bathroom, water supply, ventilation, crowding, and cleanliness.

The table on the opposite page gives the distribution of infants and infant mortality rates by occupation of father for full-term and premature infants.

The largest group of fathers consisted of unskilled laborers who formed 42 per cent of all fathers. Farmers were next with 21 per cent. Skilled workers formed 13 per cent of the total. Infant mortality was lowest for infants of farmers followed by infants of skilled workers.

The groups of skilled and unskilled workers show a remarkable difference with respect to full-term and premature infants, for while the infant mortality for full-term infants is considerably higher for the unskilled group, the reverse is true for premature infants. However, the figures are much too small for any valid conclusions. Only a little over a half of the fathers were employed full time, an additional 18 per cent were employed part time, and 16 per cent were on work relief. Nearly one-third of the families were receiving home relief. Emergency relief provided prenatal care for 19 per cent of the families. The infant mortality in the group receiving relief (67.5) was considerably higher than for the families not receiving relief (46.7).

Illnesses of Child

The schedule did not include a specific question about illnesses of child. There was one question which read "illnesses prior to that causing death" and it referred, therefore, only to infants who died. However, on many of the schedules under "remarks" the nurse noted some illnesses. It is felt that the item was not filled out completely. This was substantiated by a check of the files of the Division of Communicable Diseases which revealed a number of names of infants of the study on whose schedule no mention was made of disease.

Of the 1,474 surviving infants, 531 or 36 per cent were recorded to have had at least one illness. On the bulk of the remaining 943 schedules no mention of any illness was made but there was no statement that the infants completed the year without being ill. The 531 children

**INFANT MORTALITY BY OCCUPATION OF FATHER FOR FULL AND PREMATURE INFANTS
ST. LAWRENCE COUNTY—1935**

| FATHER & OCCUPATION | BIRTHS | PERCENTAGE OF TOTAL BIRTHS | —INFANT MORTALITY RATES— | | |
|-------------------------------|--------|----------------------------------|--------------------------|----------------------|----------------------|
| | | | Total | Full Term Infants | Premature Infants |
| Farmer | 331 | 21.2 | 42.3 | 27.2 | 15.1 |
| Skilled worker | 195 | 12.5 | 46.2 | 10.3 | 35.9 |
| Unskilled worker | 664 | 42.3 | 52.8 | 27.7 | 15.1 |
| Tradesman, employed by others | 109 | 7.0 | 55.0 | 27.6 | 27.5 |
| Tradesmen, own business | 45 | 3.1 | * | * | * |
| Professional | 44 | 2.8 | * | * | * |
| Others | 23 | 1.5 | * | * | * |
| Father deceased, ill or child | | | | | |
| Illegitimate | 35 | 2.2 | * | * | * |
| No occupation | 22 | 1.4 | * | * | * |
| Not stated | 94 | 6.0 | * | * | * |

* Rate not computed if number of births in the group is less than 100

stated to have been ill had 732 infections or 1.38 infections per ill child. There were 166 infants or 31 per cent of those reported ill who had more than one illness or had a repetition of the same illness.

Since the date of illness was generally not stated, it was not possible to show the prevalence rate by the type of feeding at the time of illness. Comparing the whole, however, the group that was not breast fed at all with that which was breast fed at least one month, it was noticed that the infants who were artificially fed from the start were ill more often. This was true for all causes except respiratory diseases. The difference in the rate was slight. Infants using raw cow's milk had a higher prevalence of practically all causes than those using pasteurized milk.

The incidence of disease was much greater in the rural than in the urban part of the county.

There is little difference in the rates for the two sexes. However, it is noteworthy that while males had a slightly higher incidence for most causes, the reverse is true for communicable diseases in which group the female incidence was higher.

Maternal Deaths

There were nine mothers who died before their infants were one year old. The infants of these mothers all survived. The interval between date of delivery and date of death was as follows:

MATERNAL DEATHS BY INTERVAL AFTER DELIVERY

| INTERVAL | NUMBER OF DEATHS |
|---------------|---------------------|
| Under 1 month | 5 |
| 1 month | 1 |
| 2 months | 1 |
| 7 months | 1 |
| 8 months | 1 |

On four of the death certificates of the five mothers who died in less than one month after delivery, puerperal causes were given as primary and on the fifth, the puerperal cause was secondary to chronic nephritis. On the other four certificates no mention was made of the delivery. Two mothers, one dying at six weeks and the other at nine weeks after delivery, died of pneumonia. One of the remaining two mothers died of acute endocarditis and the other of disease of the pancreas.

Three of the mothers who died were primiparae. Their ages were 16, 17, (an illegitimate birth), and 20. Three others had had 13 or more pregnancies. Three mothers had had a total of 7 previous stillbirths and 5 infant deaths. Their ages were 35, 40, and 41.

Some pertinent facts concerning the history of the mothers who died is presented in the table on page 326.

Summary

1 The infant mortality rate dropped during the year of study and has not returned to previous high rate.

2 Prenatal care favorably influenced infant mortality rates. Previous infant deaths and stillbirths increased likelihood of higher rates.

3 Mortality rate was higher in families in poor economic state than in good.

4 Racial stock, especially French Canadian apparently had little influence on rate.

5 Infants born in hospitals located in different town than mother's residence had higher mortality rate than infants born in same town as mother's residence.

Discussion

Dr Leo F Schiff, *Plattsburg*—A study similar to the one in St. Lawrence County was conducted in Clinton County for all live births in 1935. The two counties are very similar in many respects. They are close together in geographical location, have approximately the same composition of population, and both have had consistently high infant mortality rates. Unfortunately, the study in Clinton County was not begun until the late months of 1935, continuing through 1936, and was to a great extent retroactive, the information about most of the infants being obtained almost a year after birth. The investigation was done mostly by local nursing personnel who were not especially trained for this work nor thoroughly conversant with the purpose of the investigation, and the forms often were filled out rather routinely without sufficient questioning, and as a matter of fact the actual form of the questionnaire could have been improved upon. It is interesting to note that even under these conditions the infant mortality rate in the county dropped to its lowest point (below 60) during 1936, the year in which most of the nurses' visits were made in following up the survey, and that the following year, after completion of the study and the extra visits, the rate, as in St. Lawrence County, rose again to its former level. Since we have been told of the same results in other localities where studies of this sort were inaugurated, we may rule out the possibility of the reduction being accidental. We may

also reasonably conclude that such studies to be effective should continue for more than just one year. The Clinton County study was based on 1,021 live births, of whom 78 died under one year of age, giving a true infant mortality rate of 76.4.

The influence of age of mother and order of birth upon infant mortality was shown in the Clinton County study as in the one in St. Lawrence County, the rate being high for young mothers, at a minimum at ages 20 to 24, and increasing thereafter. Infants born to mothers who had previously had an infant death in the family showed a higher mortality than those in other families. Again the Clinton County study agrees, as might be expected, with that of St. Lawrence County in the influence of abnormalities in the mother during pregnancy on infant mortality. Prenatal care was far from ideal. The proportion of physicians taking Wassermanns as a routine in pregnancy was low in Clinton County, as it was in St. Lawrence County. The mortality of infants where the mother did not see a physician until the time of delivery was much higher than that of infants whose mothers had received prenatal care. There was the same high proportion of premature births and high mortality rate of prematurely born infants.

In reviewing the findings in the two counties, even though the surveys were not as complete or as long-continued as they might have been, certain points, nevertheless, stand out as being important factors, particularly the high percentage

of deaths due to prematurity, the larger families the longer period of childbearing for women, the rural character of the county making nursing supervision more difficult and decreasing the availability of prenatal care the increase in the mortality rate in families in the lower brackets of economic status. These all indicate where efforts to reduce infant mortality should be directed.

I would make a special plea to physicians to

refer prenatal cases to the public health nurse as early as possible. If we are to reduce stillbirths and neonatal mortality rates mothers should have help and advice early in pregnancy, not just before the time of delivery. Hand in hand with these if we are to achieve results, must go further efforts in public health education to reach those who are going to need this help and advice before the necessity is upon them.

THE GROSS PRIZE ESSAYS

The Philadelphia Academy of Surgery announces that essays for the Samuel D. Gross Prize of fifteen hundred dollars will be received in competition for the prize until January 1, 1940.

The conditions annexed by the testator are that the prize shall be awarded every five years to the writer of the best original essay, not exceeding one hundred and fifty printed pages octavo in length, illustrative of some subject in Surgical Pathology or Surgical Practice founded upon original investigations the candidates for the prize to be American citizens.

It is expressly stipulated that the competitor who receives the prize shall publish his essay in book form and that he shall deposit one copy of the work in the Samuel D. Gross Library of the Philadelphia Academy of Surgery and that on the title page it shall be stated that to the essay was awarded the Samuel D. Gross Prize of the Philadelphia Academy of Surgery.

The essays which must be written by a single author in the English language, should be sent to the Trustees of the Samuel D. Gross Prize of the Philadelphia Academy of Surgery care of the College of Physicians 19 S. 22d St. Philadelphia on or before January 1, 1940.

Each essay must be typewritten distinguished by a motto and accompanied by a sealed envelope bearing the same motto containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay.

The Committee will return the unsuccessful essays if reclaimed by their respective writers or their agents within one year.

The Committee reserves the right to make no award if the essays submitted are not considered worthy of the prize.

CO-OPERATIVE MEDICAL TRYOUT IN WISCONSIN

An experiment worth watching has been started at Superior Wisconsin by the County Medical Society there, in co-operation with the State Medical Society. The doctors of the County Society are to give complete medical and surgical care to the members of the Co-

operative Health Association of Superior on a prepayment basis for a period of trial and study. The patient has free choice of any doctor in the county society and the J.A.M.A. reports that '\$3 a month for an entire family has been tentatively considered' for the dues.

A NEGLECTED ENTITY IN ABDOMINAL PAIN AND A COMMON DISEASE—CICATRIZING ENTERITIS

ELLIOTT C. CUTLER, M.D., Boston

(From Peter Bent Brigham Hospital, Boston Moseley Professor of Surgery, Harvard Medical School)

THE disorder of cicatrizing enteritis presents a clinical entity characterized by bouts of diarrhea, fever, and attacks of colicky abdominal pain, lasting over many years, ending with weight loss, and frequently forcing patients on the advice of their family doctors to seek surgical relief. The observation of several cases over a period of years seems to indicate that surgery is not a cure, that recurrence following radical surgery is frequent, and that patients may recover spontaneously. It is our hope that the evidence is now sufficient to justify the retention of patients with this disease in the hands of the family physician and thus avoid the suffering and dangers which accompany surgical therapy.

The disease has been variously called terminal ileitis, interstitial enteritis, Boeck's sarcoid, and chronic granuloma of the intestine. Its etiology is unknown, investigators have been unable to transfer the disease to animals, and bacteria or virus as a cause are not indicated by laboratory studies. It is, however, a definite clinical entity and should be identified as easily in our day as were the disorders described by Addison, Hodgkin, Basedow, Paget, and von Recklinghausen in their day.

The disease is a chronic, nonspecific, inflammatory lesion of the intestine chronic, because it exists in individuals over many years—present twenty-three years in one case in this proved group (Z.S. below), nonspecific, because inoculation of histologically involved lymph nodes has given no growth on culture media and no "takes" in any laboratory animal, inflammatory, because local cellular reaction and fever accompany acute exacerbation of the disease.

It more commonly and usually involves the terminal ileum but has occurred independently in the jejunum and the large intestine. It usually commences in youth. In this series of 11 cases certified by histologic study, the average age was 34 years when recognized, 34.2 years in 6 males, and 33.2 years in 5 females. The average age of onset was 27 years. The occurrence in youth may suggest bacterial etiology, i.e., a disease arising before immunity is fully established. It has been more frequently reported in Jewish people—in this series 7 of 11 cases, the other racial divisions are as follows: 1 negro, 1 Armenian, 1 Italian, 1 Irish. This preponderance of the Jewish race may only reflect the fact that the chief studies thus far have come from large urban centers where the concentration of Jewish people is relatively high.

A study of the literature is of interest since it reveals that sporadic cases have been reported for twenty-five to thirty years and curious granulomata of the large bowel, even longer. In 1913, under the title, "Chronic Interstitial Enteritis," Dalziel of Glasgow presented typical cases and he referred to the similarity of his pathologic findings to those of Johne's disease in cattle. Moschcowitz and Wilensky of New York in 1923 under the title, "Nonspecific Granulomata of the Intestine," reported 4 cases where the lesion seemed restricted to the terminal ileum and cecum. But it was not until the paper by Crohn, Ginzburg, and Oppenheimer entitled "Regional Ileitis" in 1932 that the attention of the profession was seriously awakened. These authors gave the first clear description of the disease, defining a symptom-complex and pathologic entity out of that hodgepodge

Presented in part before the Interstate Postgraduate Medical Assembly of North America, St. Louis, October 19, 1937, and before the Rochester Academy of Medicine, Rochester, New York, November 4, 1937

and melting pot of benign granulomata of the intestine in which lie tuberculosis, Hodgkin's disease, lymphogranuloma, etc. They emphasized the acute, subacute, and chronic process with tubercle formation, they pointed out that patients, if they fell into the hands of surgeons early in the disease, usually lost their appendices, and they defined the clinical course of bouts of diarrhea and abdominal pain usually beginning in young adults and accompanied by chills and fever. These authors believed that the disorder was confined to the terminal ileum and advised surgery. A voluminous literature, largely case reports with clinical studies, has appeared, at least eighty four papers in the last ten years. The experimental studies of Reichert, who injected sclerosing solutions into the mesenteric lymphatics and produced tissue changes similar in many ways to those seen in this disease, are illuminating but give us no further clue. These reports have added nothing to our knowledge of the etiologic factors. Some authors report complete cure by surgical means but follow up studies in our patients and in certified cases in the hands of colleagues lead us to feel that the recurrence is a frequent happening.

Pathologic Considerations

The initial histologic lesion seems to be a generalized inflammatory reaction with increased vascularity and swelling of the involved tissues with edema and cellular infiltration, the cellular infiltration is largely lymphocytic with plasma cells and eosinophils in moderate numbers. Eventually the acute reaction is followed by fibrosis and invasion by giant cells, and a more chronic process occurs as a part of the attempted healing process. The reactive areas now appear as small tubercles similar histologically to what appear in tuberculosis. An essential difference from tuberculosis is that, though both lesions show tubercles composed of epithelioid cells and giant cells with lymphocytic reaction, the lesion in cicatrizing enteritis never contains the tubercle bacillus and never goes on to caseation. As the fibrosis increases, constriction of the

bowel results and the wall of the intestine becomes a stiff tube with variable areas of greater constriction which may almost totally obstruct the lumen of the bowel. In the large intestine the fibrous tissue reaction tends to be greater than in the small intestine, and actual tumor masses which are palpable and even visible through the abdominal wall may result. In the small bowel, as the constriction progresses and as the blood supply and lymphatic drainage are interfered with, ulceration of the mucosa results. This ulceration has a highly characteristic appearance being located at the mesenteric side of the gut, often as a long irregular ulceration about which the gut is constricted. The majority of the reports agree that the terminal ileum is by far the most frequently involved area.

Clinical Considerations

The pathologic process gives us ample and complete understanding of the clinical course of such cases. Clinically, the history is that of young people with at first intermittent bouts of diarrhea and vague abdominal distress, such bouts often accompanied by fever. If the abdominal distress is considerable attention is called usually to the right lower quadrant, since the chief focus in most cases is the terminal ileum. It is because of this that so many of the cases have had their appendices removed during an early attack—in our series, 5 of the 11 cases. Once the disease is established, the bouts of diarrhea, pain, or indigestion repeat themselves and eventually the diarrhea results in considerable loss of weight. In 6 of our 11 cases the weight loss averaged 23 pounds before the diagnosis was made. Gradually stenosis of the bowel occurs and the patient, perhaps long treated as a case of tuberculosis of the intestine or ulcerative colitis falls into the hands of the surgeon and usually exploration reveals the disease.

More rarely there is a seemingly acute onset as perforation occurs. In a review of our cases many of the patients upon early admissions were diagnosed as tuber

culosis by the roentgenologist as well as the physician. Others were thought to be suffering from ulcerative colitis. One patient had been in the hospital five times previously for study, 3 patients, four times, 1, three times, 1, twice, and 1, once, and 3 of the 11 patients had been in sanatoriums for tuberculosis. We must remember that clinically they presented themselves as wasted young people with diarrhea, and that the x-ray studies revealed an irritated terminal ileum and cecum so frequently the seat of intestinal tuberculosis or chronic ulcerative colitis.

If we, as surgeons, are to be critical of others, we must be equally critical of ourselves for not recognizing the disease earlier. Of course all surgeons have handled this entity and we feel chagrined at our failure to have noted the disorder until colleagues had published their studies. But if we as surgeons have been guilty, surely our pathologic and roentgenologic confrères are in a similar predicament. An industrious search among our cases of so-called chronic appendicitis by Dr Orville Bailey yielded only one case (Z S, reported below) in which the excised specimen suggested the disease on histologic grounds, and a careful follow-up on patients in whom there was evidence of irritability of the terminal ileum and cecum and in whom tuberculosis has been suspected but not proved yielded no case of this disease and only two changes in diagnosis, one from tuberculosis to cancer, and the other from tuberculosis to amebic dysentery. These studies seem to suggest an increasing incidence of the disease.

Case Reports (See chart, opposite page)

Case 1—M M G * Jan 3, 1925. Original admission when 25 years old with a complaint of diarrhea of eight months' duration. No blood in stools, slight abdominal cramps. In spite of diet there had been a loss of 30 lbs in weight. For five months before admission he was kept to his bed. In the hospital his diet

was changed and he was discharged improved. Impression chronic colitis. April 7, 1926, re-admitted. This time there was fever in addition to diarrhea. He had gained some weight. There was occasional nausea and vomiting and a relative mononucleosis. Temperature gradually fell. Discharged. Impression infectious mononucleosis. June 29, 1926, re-admitted for tonsillectomy. Jan 6, 1929, re-admitted for fever of unknown origin, diarrhea had continued. X-ray studies (barium enema) suggested tuberculosis of the cecum. Sept 11, 1931, re-admitted. Again there was diarrhea, lower abdominal pain, and fever. The patient was explored and the cecum, ascending colon, and 120 cm of terminal ileum removed (Sept 15, 1931). Diagnosis terminal ileitis. April 5, 1933, in for check-up on condition. Bowel movements had decreased for several months following operation but gradually increased thereafter until he had as many as 30 movements a day. No gross blood in stools. Barium enema studies showed colon to fill normally, the hepatic flexure to regurgitate promptly into ileum, the distal ileum to appear irregular and irritable. Recurrence of disease suspected. Sept 2, 1933, patient again submitted to surgery after study. This time a good deal of the terminal ileum was again involved and it looked as if it would be impossible to resect. Picking up a piece of ileum some 15 cm away from the present stoma, a new ileo-transverse colostomy was done close to the splenic flexure, leaving a loop of ileum and a segment of transverse colon in the patient through which, however, the intestinal stream did not necessarily have to pass. The patient made a good postoperative recovery and then moved to New York where in March, 1934, he was operated upon again. The proximal ileum between the two ileotransverse colostomies was excised after the proximal ileo-transverse colostomy was taken down and the opening into the transverse colon closed off. July, 1935, and May, 1936, he was again back in this hospital. He had gained weight, but diarrhea and abdominal pain gave evidence that the disease was still present. Nov., 1936, check-up showed he had gained 30 lbs, but still had abdominal discomfort and diarrhea. Barium enema showed recurrence in the ileum. A check-up in April, 1937, showed the same results as in November, with 6 stools a day. Oct 13, 1937, gave his weight as 137 lbs stripped. He had 3 stools a day. Barium enema showed 40 cm of terminal ileum rigid and constricted, average lumen only 8 mm. Impression disease still present and active.

* Previously reported by Dr John Homans and Dr George M Haas

SUMMARY OF CASES

| | DATE AND AGE AT RECOGNITION | PRESENTING SYMPTOMS AND DURATION | HOSPITAL ADMISSIONS BEFORE RECOGNITION | PRE EXISTING APPEN DECTOMY | OPERATION* | FOLLOW UP |
|------------------|-----------------------------------|---|---|-------------------------------------|---|---|
| M.M.G. male | 1931 31 yrs. | Diarrhea abd pain 7 yrs. wt. loss 30 lbs. | 4 | 0 | 1 0/15/31 Resec. 4 foot ileum append. ascend. colon ileotrans. colostomy 2 10/2/33 Sidetracking ileotrans. colostomy | 1 1 yr later more ileum excised (N.Y.) re- ported "cured" 2 10/13/37 gained 30 lbs "frequent stools" x-ray narrowing ter- minal ileum. * These cases were operated upon by Drs. John Homans, Robert Gross, Carl Walter and Elliott Cutler of the Peter Bent Brigham Hospital Surgical Staff

Case II—G.B. † March 1933 patient 20 years old, with history of recurrent left lower quadrant pain and diarrhea of two years duration. Spasm, tenderness in right lower quadrant. X-ray studies showed terminal ileum narrow and constricted over several inches ileocecal valve tender Impression probably tuberculosis. Operation revealed lower 3 cm of ileum much thickened edematous and constricted Coils adherent enlarged retro-peri-

tonal glands Excision lower 5 cm ileum appendix cecum and ascending colon lateral anastomoses to transverse colon Feb 28 1936 check up showed no discomfort gaining weight occasional attack of diarrhea. Feb 7 1937 barium enema showed large bowel normal to ileocolostomy barium could be forced into ileum which seemed normal Feb 14 1937 week preceding had had attack of severe right lower thoracic pain radiating to back. No previous gallbladder history but this was considered. Feb 25 1937 cholecystograms showed

† Previously reported by Dr. John Homans and Dr. George M. Hanz.

normal gallbladder Feb 28, 1937, no return of pain Sept 2, 1937, occasionally had formed stools with 3 to 4 bowel movements a day Appeared well, abdomen negative Impression disease still present

Case III—A S May, 1934, patient 60 years old For ten years had had attacks of pain in the right lower quadrant with some loss of appetite and weight Physical examination showed tenderness in the right lower quadrant, barium enema showed narrowing, irritability, and distortion of the ascending colon, the terminal ileum appearing normal Patient explored Ileocolostomy, sidetracking operation carried out He was not a good risk The wound eviscerated and the patient died six days postoperatively Histologic report cicatrizing enteritis

Case IV—D.A.R. Oct, 1935, patient a 20-year-old student nurse Admitted complaining of intermittent pain of one year's duration Two years previously had intractable diarrhea, blood, and mucous, which gradually became worse, accompanied by dull right lower quadrant pain, distention, and gas Diagnosis chronic appendicitis Operation performed elsewhere one year after onset Diagnosis of intestinal tuberculosis made, not proved histologically Diarrhea first improved, then an ischio-rectal abscess developed The sinus had been present about eight months X-ray studies, barium enema, showed irritable lesion in terminal ileum Under spinal anesthesia ischio-rectal fistulous tract excised proved tuberculous Fever and bowel complaints continued Because of proved tuberculosis of the fistula and the fact that tubercle bacilli were said to have been found in the stool on occasions, and because the appendix was thought to be tuberculous, the diagnosis of cecal tuberculosis was made Patient explored Dec 5, 1935 Terminal ileum was found to be repeatedly kinked and adherent upon itself, and there were greatly enlarged lymph nodes in its mesentery Tubercles were seen on the surface of the large bowel No free fluid Resection 5 cm terminal ileum, cecum, and part of ascending colon, end to side anastomosis Good recovery, steady gain of weight, 30 lbs by Nov 5, 1936, at which time anal wound was still open There was some diffuse lower abdominal tenderness, occasional bouts of diarrhea Histologic report cicatrizing enteritis, not tuberculosis April 26, 1937, office examination a week previously showed a gain in weight to 166½ lbs, but there was a tender mass in the right lower quadrant and patient still had bouts of diarrhea Rectal examination inconclusive, rectal wound well healed, pilonidal sinus quiet

Barium enema on April 26 showed definite involvement of small fragment of ascending colon Terminal ileum was unable to be filled with barium Recurrence May, 1937, diarrhea continued Oct, 1937, diarrhea still continued Patient had gained more weight. She was working as a nurse Impression recurrence of disease

Case V—A C W Dec, 1935, colored female of 47 years entered the medical service complaining of shortness of breath and loss of voice of one week's duration For three months there had been unproductive cough, occasional fever, and poor appetite There had been diarrhea for five months, and she had lost 29 lbs in five months As a part of the general check-up on her condition a barium enema was done which to everyone's surprise showed an obstructive lesion at the midtransverse colon The diagnosis of obstructing carcinoma was made Transferred to surgery Exploratory laparotomy revealed a peculiar inflammatory obstructing area in the midtransverse colon region, which certainly was not a typical carcinoma. Because of uncertainty of type of lesion, it seemed unwise to resect and perform a primary suture Most of the transverse colon was dragged out of wound, and the loop containing the lesion removed with its web of mesentery The two loops of bowel were then approximated and a Mickulicz procedure carried out Convalescence uneventful Histologic studies proved entity to be cicatrizing enteritis Patient made a good recovery Was well until Oct, 1936, when there was pain about umbilicus and a tender lump at the bottom of the scar Nov 30, 1936, re-admitted to surgical service but preferred to go home for Christmas X-ray studies showed constant irritability at transverse colon at point of previous operation suggesting that the disease was still present at this point Jan 4, 1937, re-entered Old wound re-opened At bottom of wound the bowel was firmly adherent to the scar, and the mass which had been felt seemed to be an extension of the disease into the subcutaneous tissues The scar itself, therefore, was left on the bowel mass Exploration revealed that, although this had not been seen a year before, the disease now involved the cecum, the appendix, and about 3 cm of the ileum There were involved lymph nodes in the mesentery, the gut was thickened, puckered and edematous, and in part stenosed Radical removal decided upon Ileum divided 5 cm from ileocecal valve, and terminal ileum, appendix, cecum, ascending and transverse colons excised, cutting across the mid-descending colon It was then found that the entire sig

mold was involved and the patient was left with a permanent ileostomy closing off the distal end of the divided sigmoid. Patient seen March 5 1937. Was gaining weight rapidly. By April 20 1937 she had gained 43 lbs. the ileostomy worked well and there were no complaints. Three enemas were given after leaving hospital but only slimy material had come away. Felt better than ever and ate well. Barium enema, which included only sigmoid since that was the only fragment of large bowel remaining, showed large bowel pliable movable, haustrations re-appearing in contrast to a fixed stiff tube seen previously. The small perforation seen before the last operation when the barium tended to escape into the left iliac fossa had disappeared. Great improvement. On Sept. 30 1937 barium enema showed normal rectum and descending colon. Patient had gained 49 lbs. Ileostomy moved twice a day. She felt fine. Impression: excellent result. No evidence of recurrence.

Case VI—B.D.W. Feb. 2 1932. 21 years old came to hospital complaining of intermittent bouts of diarrhea for six months. Barium x-ray studies seemed practically normal. Placed on a diet. July 14 1936 re-admitted complaining of abdominal pain of greater intensity than usual for two days before admission. White count had risen to 14,200. Barium studies disclosed an irritable terminal ileum. Diagnosis: regional ileitis. Dietary regime ordered to be continued. On Oct. 13 1936 re-entered hospital because of two attacks of severe abdominal pain with fever and diarrhea. A fusiform nontender mass was felt in right iliac fossa. Operation Oct. 16 1936 resection of terminal ileum and cecum for typical cicatrizing enteritis. By Dec. 1936 he had gained from 126 lbs. to 144 lbs. Condition excellent. Belladonna taken in small amounts. One stool daily sometimes every other day. Check up on April 16 1937 patient had been to Florida. Had gained 30 lbs. since operation but still had attacks of diarrhea and abdominal pain, without chills or fever. No x-ray check up made. Impression: disease still present.

Case VII—D.S. Oct. 6 1927 entered the Peter Bent Brigham Hospital at 18 years of age. Apparently typical attack of acute appendicitis. operative findings compatible with acute appendicitis. histology showed acute appendicitis. Not seen again until Aug. 2 1933 when he entered the medical service with complaint of diarrhea of one and one-half years duration. cramplike pains over whole abdomen, occasional nausea and vomiting. loss of 28 lbs. Stools negative for typhoid paratyphoid and dysen-

tery. X-ray enema showed some delay at splenic flexure and remaining colon and distal ileum was filled with difficulty. Impossible to outline cecum. Impression: tuberculosis of the terminal ileum and colon. Studies repeated and it was thought that the too oblique appearance of terminal ileum with irritability and with general narrowing of colon suggested ileitis and colitis, probably nontuberculous. Discharged on bland diet. Nov. 4 1933 re-entered medical service with diarrhea worse than ever in spite of carrying out dietary orders. Given emetine therapy with negative results. In spite of x-ray opinions, medical service felt the disease might be acid fast enteritis and the patient was transferred to the Lakeville Tuberculosis Sanatorium where he remained from Dec. 19 1933 to April 15 1934. All this time he was bothered with bouts of diarrhea and abdominal complaints. Re-entered the surgical service on Nov. 19 1936. Symptoms had returned, and continued. Just before admission, sharp right lower quadrant pain on several occasions. Surgery advised. At operation definite evidence of chronic cicatrizing enteritis over the lower 40 cm. of the small intestine. Cecum and ascending colon were fixed, thickened, and firm, and there was some involvement of the whole transverse colon. The lower 60 cm. of the small intestine with cecum, ascending colon, transverse colon and half of descending colon were removed and a side to side ileocolostomy carried out. By Feb. 12 1936 patient weighed 147 lbs. and felt fine, two or three stools a day, no pain, abdomen soft. He was working. On Feb. 17 1936 a barium enema showed no evidence of disease. Check up on March 1 1937, showed patient was working that he felt fine, had liquid stools but no abdominal discomforts. Halliveroll and yeast prescribed. From May 28 to June 12 1937, patient was in hospital for diarrhea 7 per day. Barium enema suggested partial obstruction at various parts of small intestine. By June 22 1937 he was having 3 stools a day. Impression: recurrent disease? Inactive.

Case VIII—Z.S. Aug. 1921 patient 18 years old came to hospital complaining of attacks of abdominal pain. Had had malaria nine years previously and an attack of jaundice two years previously. Bouts of abdominal pain had been present for eight years occurring every four to five months i.e. began at 10 years of age. Physical examination negative except for umbilical hernia. Explored Aug. 26 1921 routine appendectomy. Appendix normal. findings quite normal except for umbilical hernia. Patient was not improved by surgery.

and in Dec, 1926, was back in hospital in the medical service with same complaint, though in addition he had noticed bouts with more pain and sometimes chills, fever, and diarrhea. It was suggested that he had mucous colitis. Cholecystograms and G.I. x-ray studies were negative. In medical record on Feb 6, 1928, a letter from D H J said this patient went to Dr H H G who explored him finding a peculiar condition with inflammation of the lower abdomen involving cecum. Some adhesions were cleared and after a strenuous convalescence, patient recovered. Letter from patient's New York doctor April 13, 1937, said x-rays in New York showed an apparent narrowing of the terminal ileum a few inches distal from the ileocecal valve. Oct 13, 1937, correspondence revealed that in another x-ray series in June, 1937, the irritability seen previously had disappeared, but patient still had bouts of diarrhea. Impression: disease still present.

Case IX—NW In 1928, when 20 years old, had appendectomy at the Harley Hospital. Apparently no complaints preceding the acute story. In Sept, 1935, at the Beth Israel Hospital, because of left-sided pain in abdomen, was proctoscoped and studied, and discharged without diagnosis. He came to the Peter Bent Brigham Hospital in Oct, 1935, complaining of lower abdominal pain. Barium studies revealed irritable cecum. He was admitted to the surgical service at this hospital in March, 1936, complaining of hemorrhoids and rectal pain, also a left inguinal hernia. At this time careful questioning elicited the story that for at least four years he had been troubled with bouts of diarrhea and dull pain in the left flank, and ? blood and pus in stool. Anal sphincter was dilated for cure of fissure. In June, 1936, he was admitted to medical service with constant diarrhea. Carefully studied, proctoscoped, and x-rayed, and sent out with the questionable diagnosis of ulcerative colitis or psychoneurosis. Barium studies on the surgical service in August, 1936, suggested disease about the cecum. Operation was performed: adhesions were found about the seat of the old appendix scar but the intestines themselves appeared absolutely normal. Resection not carried out. By Jan, 1937, he was back on the surgical service for repair of ventral hernia in the scar through which the appendix had been removed in 1928. In spite of the fact that at the preceding operation in Aug his intestines had appeared normal, the lower $\frac{3}{4}$ of the small intestines were now found densely matted together, fixed, and beyond all thought of surgical removal. Wound closed Feb 26,

1937, he weighed 151 lbs. had many abdominal cramps, was using enemas for bowel movements. Patient brought back on medical service in March for an attempt to study his reaction to a foreign serum, Coley's serum being administered at that time. His weight was 153 lbs. He was using oil to move bowels, 1 to 2 stools a day, no cramps. March 8, first injection Coley's vaccine 0.06 cc in 1 cc salt solution first, then 1 cc in buttock, followed by dizzy spell. By March 10, 1937, diffuse pains, chills, and fever to 101 F. March 12, 1937, had diarrhea for one day. March 26 entered hospital and that day and as follows (March 30, April 1, 4, 6, 9, 12, and 14) Coley's serum intramuscularly. Injections 1, 6, 9, 12, and 14 accompanied by chills and high rise in temperature. Meanwhile he had no diarrhea. Looked well. Abdomen seemed distended but not tender and except for complaints which might have been due to the injected material, seemed well. Agglutinations for *Brucella abortus*, negative. By April 27, 1937, there was obvious involvement of the transverse colon and terminal ileum though terminal ileum peculiarly enough seemed wider, more flexible, and less involved than at the previous examinations. From Sept 10 to 18, 1937, patient was in hospital for abscess in axilla and diarrhea. Barium enema and motility series showed some healing in terminal ileum, transverse colon normal. Impression: improved but disease still present.

Case X—TF Jan, 1937, a 20-year-old single female cosmetic worker entered the medical service in this hospital with the complaint that for three and one-half years she had had recurrent attacks of right lower quadrant pain, recently more severe, accompanied by diarrhea and loss of weight to 83 lbs. On admission a mass was felt in right lower quadrant. Barium studies both by enema and by mouth showed inflammatory lesion involving terminal ileum, cecum, and ascending colon. Operation: resection 5 cm terminal ileum, cecum, appendix, ascending colon, and one-half transverse colon, end to side anastomosis. On March 15, 1937, motility x-ray series of 2- to 3-hour films showed an irregular loop of terminal ileum in the right lower quadrant about 10 cm in length which did not show normal mucosal markings. Patient had gained 3 lbs in previous week. March 26, 1937, she weighed 99 lbs, was having stools about three times a day, improved. September 2, 1937, a barium enema was normal. She had gained 27 lbs now weighing 110 lbs. Impression: no evidence disease, ? cured.

Case XI—LN April 21, 1937, a 54-year-old female entered the hospital because of a

ragging pain in the right flank and right lower quadrant of seven or eight months' duration. The pain had not been severe enough to interfere with her routine activities and was characterized as being a rather dull ache with a sharp stabbing exacerbation on numerous occasions. The patient had tended to have diarrhea during the past few years but it had not been enough to bother her. No chills, no fever, no weight loss. The patient had had repeated barium enemas and abdominal plates in our O D D, the results of which were equivocal. She entered the hospital for intestinal motility series. The physical examination revealed a well-developed, somewhat obese, white female in no distress. Examination was unremarkable except for the abdomen which revealed generalized right-sided tenderness more in the right lower quadrant ill-defined tender mass freely movable in the right lower quadrant. Impression chronic cicatrizing enteritis? tuberculosis of cecum? carcinoma of cecum. X-ray report April 22 hourly films after 30 grams of barium by mouth showed fairly rapid progression of the barium through the small bowel filling the cecum and ascending colon at four hours. As far as seen the loops of ileum were quite normal. Cecum and ascending colon again appeared irritable. Findings negative except for irritability in the ileocecal region. On April 24 1937 a laparotomy was carried out. Cecum and terminal ileum extensively involved with cicatrizing enteritis, routine appendectomy carried out. Appendix failed to show histologic proof of gross diagnosis. On Oct. 11 1937 a barium enema showed cecum and ascending colon ragged and irregular but more tolerant apparently improved. Impression disease still present.

Discussion

A study of these cases seems to make the symptom-complex one we all should recognize. Both the clinical and pathologic findings are highly suggestive of a definite entity and we can only wonder why this awaited recent times for recognition. The disease is characterized by a nonspecific inflammatory reaction in the intestines which usually begins in youth and goes on for years and years. It results in bouts of diarrhea and abdominal discomfort, bouts which in advanced cases are frequently accompanied with chills and fever. The chronicity of the disorder is visualized in the patient Z S (see

above) where the disease has caused symptoms for twenty seven years. Finally, as the pathologic process goes on to cicatrization, a variable stenosis of the bowel which seems to justify mechanical intervention results.

In our complete hospital series of 11 certified cases, all but 2 cases show active disease following surgery. The period of postoperative observation averages over three years. We have as controls for this series of cases treated by surgery not only the case Z S cited above in whom only incidental appendectomy was carried out and L N cited above in whom appendectomy alone seemed wise, but also four other patients in whom the diagnosis was confirmed by both clinical appraisal and x-ray studies. Note that in the case of Z S the disorder has been present for twenty seven years, yet the patient is active and well except for occasional bouts of diarrhea and colic.

Of our unoperated cases, E P is the most enlightening, for the therapeutic test was formidable, surgery being withheld because the patient's condition was so critical. The story is as follows. E P, married woman of 52, admitted for study March 20, 1933, complaining of epigastric distress and colic for four months, tenderness right lower quadrant, cholecystography, pyelography, and gastrointestinal barium studies, negative. Dec. 24, 1930, readmitted. In interim had suffered from bouts of crampy, colicky pain, most severe attack day of admission, T P and R elevated, WBC 12,000, 90 per cent polys, abdomen generally tender and spastic. Condition gradually quieted down and x-ray showed irritable ileum with multiple constrictions. Surgery withheld. Condition slowly improved, abdominal signs disappeared. Repeated x-ray studies have visualized the progress. October 7, 1937, third motility series revealed a definitely more normal appearance of loops of small intestine, irregular appearance gone, some areas of constriction remaining. General condition excellent, holding weight, active and except on rare occasions, no abdominal signs or symptoms. Impression marked im-

provement, though disease still present

A critical survey of our experience leaves us dubious about the value of surgery. Sidetracking procedures both in our hands and others have proved of little value. In this series 9 of the 11 cases were submitted to radical surgery with removal of variable lengths of both small and large bowels. Appendectomy alone was used in two cases, one where the disorder was unrecognized (Z S) and the other where radical surgery seemed impossible (L N). Radical removal usually ended with recurrence except in the most severe case of A C W when ileostomy, even with evidence of disease in the segment of sigmoid, brought prompt relief. It is unfortunate that we have had no further experience with permanent ileostomy, because the course of this disease and chronic ulcerative colitis are so alike and because permanent ileostomy in some hands has proved the most efficacious treatment for this latter condition. The apparent relief in L N when the appendix alone was removed may be only a temporary result. In the hands of others the simple procedure has not brought relief.

Throughout the citation of the cases we have spoken of an x-ray "motility series." This method has long been employed for the study of disorders of the small bowel, and consists of giving to the patient 30 grams of barium and then taking hourly films for eight to ten hours. This seems to be the best method for evaluating disorders of the small intestine and is an interesting example of the beneficial resurrection of a neglected method of study. For the adequate study of this particular entity it seems to be of the greatest value. Barium enemata may not pass the ileocecal valve and thus will fail to reveal disease in the terminal ileum. Considerable evidence, however, as we have seen, may be derived from this simple method, the motility series.

In the literature are cited cases where rupture has occurred and fistulous tracts have followed surgery. This has not occurred in our experience in spite of frequent re-involvement at the site of surgical intervention. In fact our only ex-

perience with fistulae was in a case not reported here, carried in our files for two years as cicatrizing enteritis, finally proved to be the seat of malignant disease.

It has been suggested that we are dealing with a new disease or an endemic disorder recently transported among us. This does not hold when we consider the evidence of its presence long ago as seen in the literature. Its similarity to John's disease of cattle led us not only to fruitless attempts to transplant it directly to calves but to carry out skin sensitization tests with Johnin, a byproduct of the growth of the pseudotubercle bacillus of cicatrizing enteritis of cattle put out by the U S Dept of Agriculture for animal testing. We gave intradermal injections of this preparation to five patients with proved cicatrizing enteritis and four normal individuals, using tuberculin, salt solution, horse serum, cow serum, and tetanus antitoxin for control of the zone of reaction.

Severe abnormal reactions occurred in only two cases, one patient with a proved tuberculous fistula showed a positive reaction to tuberculin, and another patient recently given a prophylactic dose of tetanus antitoxin showed a positive reaction to tetanus antitoxin. The patient sensitive to tuberculin was also sensitive to Johnin, and three other patients with cicatrizing enteritis and three of our normal controls were sensitive to both Johnin and tuberculin. Obviously there is no relationship between skin sensitivity to Johnin and to cicatrizing enteritis of man, though there is a positive correlation between skin sensitivity to tuberculin and skin sensitivity to Johnin.

Therapy other than surgery has consisted only of a simple bland diet. Drugs have not been of great value. Liquid petrolatum has helped where there have been signs of obstruction, and in the acute phase frequent small feedings have alleviated the difficulties and fear of a large food intake.

Coley's serum was given in one case without great change.

Reactions to *Brucella abortus* and the Frei test have been negative.

Summary—1 Cicatrizing enteritis is a striking clinical entity characterized by bouts of diarrhea and colicky pain, and often accompanied by chills and fever

2 Eleven surgically treated and histologically certified cases of cicatrizing enteritis are discussed, with citation of nonoperated cases with the same disease.

3 Nine patients show recurrence, after radical surgery. Some patients have had multiple operations. One case with severe recurrence has been cited by his previous physician as cured.

4. Two patients with simple appendectomy and proved disease are still the seat of disease, one after twenty seven years, but both are active and in good general condition. One patient with the most extensive evidence of involvement by x ray is steadily improving without surgery.

5 A "motility" x ray series is the most important method for the proper evaluation of this disease in the small intestine.

6 We advise against surgery unless

action is forced by obstruction or perforation

7 If surgery seems necessary, permanent ileostomy may be the best procedure.

8 We feel patients with the seat of this disease should be recognized by family physicians who should keep such patients under their care on a simple diet rather than turn these patients over to their surgical colleagues

THEY ARE DISCOVERING THE SNAGS

It is doubtful if the health insurance scheme enacted in Australia a few months ago will ever go into effect says a letter from that country to the *J. A. M. A.* The medical profession there is strongly against it, not merely on financial grounds, but because it will not provide a satisfactory medical service. Apart from the opposition of the medical profession the government is meeting severe criticism from other quarters. First, from a strong federal labor opposition, second from a section of employers who regard with misgiving the extra cost that they will have to carry as contributors to the scheme on behalf of their employees. third, from a body of rural opinion which voices the grievances of small farmers, who will be required to pay contributions for persons they employ but who will not themselves, as self-employed persons be eligible to become insured, and, finally from the existing friendly societies.

FIGHTING PNEUMONIA BY MOVIE

A movie is the newest weapon of the New York State Department of Health in its war on pneumonia. It is titled, "Serum to Windham" and is being shown at local movie theaters throughout the state.

"Serum to Windham" is a true story based on an actual happening in the Catskill Mountains where a youth was stricken with a rarer type of pneumonia. Realizing the importance of the prompt diagnosis and treatment, a country doctor set emergency wheels in motion. Laboratory New York City police, railroad workers state troopers, and others participated in getting the serum to Windham in time to save the youth's life. Blizzards, snow drifts and sub-zero weather faced the men delivering the serum.

Some of the persons who took part in the real life drama are included in the cast of the film which was produced by the Division of Public Health Education, State Department of Health

SURGICAL TREATMENT OF SPASTIC PARALYSIS

FREMONT A. CHANDLER, M D , Chicago

THE term "spastic paralysis" refers to a greatly varied symptom complex, in which the hypertonicity of the skeletal muscles and distorted muscle control are the outstanding features. Because of the wide variety of classifications, considerable confusion has resulted in the various terminologies. By general usage, the term "spastic paralysis" is applied to that paralysis resulting from birth injury or prenatal pathology. In this paper, however, the spastic picture following trauma or the result of other pathologic processes will be touched upon.

The statements made by W. J. Little in 1843 in his publication, *Nature and Treatment of the Deformities of the Human Frame*, still hold true.

"The effects of the derangement of the brain or cord may be limited to the functions of a single muscle or a larger number of filaments and more muscles may be affected."

"May present itself as a congenital affection or as a result of disease during infancy. It is often difficult and sometimes impossible to discriminate."

"In some instances, however, the weakness of intellect appeared to result less from permanent injury to the brain than from want of sufficient training and education."

"The deteriorated health of the parent had directly impaired the nutrition of the fetus, and both directly and indirectly the healthy development of the nervous system."

"An infant prematurely born inadequately prepared to contend against the operation of external agents altered function, congestion, or disease of the most susceptible of the infant's organs, those of the nervous system should occur."

What can modern science add to these

statements of nearly a century ago?

In general, spastic paralysis, or Little's disease, may be described as a disease, congenital or acquired, resulting from sclerosis of cells of the upper motor neurone, varying in degree and usually causing a hypertonicity of the muscles of the part affected. Orderly inhibitory stimuli of central origin do not reach the primary reflex arcs. In contrast to the more or less constant picture of hypertonic muscle reaction are the bizarre entities which we group under the general term of choreo-athetosis. In these, control of purposeful motion is distorted. Little's disease presents a picture of disturbed function of the corticospinal (pyramidal) tracts whereas the latter group presents disturbed function of the tracts from basal nuclei (extrapyramidal) tracts. An overlapping of these clinical pictures occasionally occurs.

The gross or histopathology of spastic paralysis which has been described by many writers may be summarized as follows. When associated with brain injury the lesion is usually found located on one or both sides of the brain and consists of a sclerosis or softening of the area involved, resulting in a degeneration of the cortical spinal tracts. When due to arrested development, the gross evidence is prominent in the cortex as shown by a more primitive convolution pattern. Frequently this is absent and the pathologic picture is present only on microscopic examination. When associated with a disease such as syphilis, there is an associated meningomyelitis of vascular origin with a resulting scarring and adhesions of the membranes and invasion of the brain and cord substance.

When seen at postmortem, the brain surface presents a picture of neuroblastic death as evidenced by atrophic sclerosis

*Read by invitation at the Annual Meeting of the Medical Society of the State of New York,
New York City, May 11, 1938*

and degeneration of the brain substance as a secondary gliosis

1 A localized lesion of the brain cortex or a small lesion involving the converging cortical spinal tract may be located at or near the internal capsule. These small localized lesions will give focal symptoms involving one or part of any of the extremities and trunk.

2 Scattered pathology This is chiefly prefrontal in origin in the temporal or parietal lobe and is more frequently associated with gross mental defects.

3 A diffuse (walnut) brain in which the frontal and occipital gyri are hard shrunken, and leathery. The cerebellum is usually normal. It may be associated with cavity formations within the brain substance or marked enlargement of the ventricles, probably a process which starts in the deeper cortical layers and is probably a manifestation of embryologic vascular rests.

4 Corpus striatum changes, confined to the caudate nucleus and putamen and the basal ganglia, causing bilateral athetosis and chorea. They are thought to be a prenatal process. A similar lesion in the premotor area is usually responsible for the choreiform athetoid movement found in so many spastics.

5 A vascular change is often encountered and is evidenced by scarring following a periarteritis or a cortical venous thrombosis.

Any one or all of the above complications may be present in the same individual, each resulting in a loss of the inhibitory function of the upper motor neuron.

The title of this presentation, 'Surgical Treatment of Spastic Paralysis, would better read, Surgical Phases of the Treatment of Spastic Paralysis,' for in the consideration of these pathetic patients the many phases of treatment should be kept in mind. Surgery plays but a minor role, serving to overcome some of the otherwise insurmountable obstacles of the more normal development and functioning of the spastic patient. When confronted with a spastic patient, the orthopedic surgeon must control his

urge to resort to surgery. He must evaluate the possibilities of the improvement which always accompany growth, the potentialities of mental development, the general state of health of the patient and the possibilities of improvement under a strict regime of physical therapy. Other than in the rare instance where heroic measures are indicated to remove cerebral blood clots, no surgery should be resorted to until the patient reveals some manifestation of co-ordination of muscle action.

During this stage, which may last from a few weeks to several years, treatment should consist of general nursing and the establishment of a proper medical regime as well as properly directed physical therapy. Probably nothing is more important in this phase than the adjustment of the parents to the burden that confronts them. Firm but guarded assurance that muscle control will definitely improve with growth may be given. All reasonable attempts of improvement of nutrition and the correction of other pathology, such as hypertrophied tonsils, etc., should be carried out. Correction of ocular defects by the use of lenses is highly advisable if the patient's condition will permit the wearing of glasses. In our clinic all spastic cases are examined by the Department of Ophthalmology and the results are most gratifying.

Open surgery is not indicated except for the correction of some definite obstacles of progress. As spontaneous muscular co-ordination advances, characteristic deformities become manifest. If these are constant and progressive in degree, their correction by surgery should be contemplated. Surgery in spastic paralysis should be carried out according to the following axioms:

1 The deformity or disability must be static, progressive, or diminishing so slowly that recovery is not to be expected.

2 The disability must be constant in its manifestations.

3 The interrelationship of multiple deformities must be understood.

4 The benefit to be had by surgery must justify the risk.

5 Sufficient time must elapse between

surgical procedures to permit the re-establishment of a constant clinical picture

6 Methods of treatment other than surgical should not be neglected

7 The patient should be fortified for surgery by every means possible

Overactivity of the adductor muscles of the thighs is undoubtedly of first importance in its effect upon the function of the lower extremities. Scissors' gait or position of the legs is indeed an obstacle to progression as well as a definitely contributing factor to flexion deformity of the knee. Overactivity of the adductor groups is indirectly associated with the production of gross deformities of the feet, for, with the foot fixed by weightbearing, adductor action results in pronation and a gradual breaking down of structures supporting the longitudinal arch. In extreme instances, this resultant force is reflected in the development of severe hallux valgus deformity. Each of these deformities is, of course, influenced by overactivity of the internal rotators and muscle imbalance about the knee and ankle as well. Because of the major role of adductor overactivity in distorting the entire weightbearing line of the leg, its correction is of first importance. In our experience, stretching of the adductor group of muscles gives only temporary benefit at best. The same may be said of tenotomy or myotomy of the origin or upper part of the adductor groups. It is obvious that, when contractures have developed rendering active or passive abduction impossible, these later procedures must be employed. Conversion of the spastic paralysis of this muscle group to a flaccid paralysis by neurectomy is most beneficial. This is done most frequently by locating the anterior and posterior branches of the obturator nerve by dissection between the uppermost portions of the adductor longus and the pectineus. The anterior branch lies in front of the adductor brevis muscle while the posterior branch lies behind it. If both of these branches are divided, a satisfactory result is obtained. The posterior branch penetrates the external obturator

muscle at various levels and because of this, may be difficult to locate. Our results with this operation were fairly satisfactory. This procedure has been abandoned for the simpler and more uniformly successful resection of the main obturator nerve just proximal to the obturator fascia (Selig operation). This procedure is simple and most effective when carefully done.

In bilateral resections a transverse (Pfannenstiel) incision is made in the lowest transverse skin crease just above the pubis exposing the anterior sheaths of the rectus abdominis muscles. The sheath of the rectus is then split vertically over the center of the distal portion of the muscle. The lateral portion of the rectus sheath is then reflected and the lateral margin of the muscle outlined. This is retracted medially. The index finger is used as a blunt dissector following the posterior surface of the rectus to its insertion in the horizontal ramus of the pubis, then more deeply and laterally displacing the bladder and peritoneum posteriorly until the obturator nerve is palpated as it lies within the pelvic wall. Flat retractors are then inserted and the fatty areola tissue is gently opened. The nerve is easily located and may be identified by its position as it enters the neural foramen of the obturator fascia or by stimulation of the nerve. The nerve is then separated from the blood vessels that accompany it by means of a blunt hook. A ligature is placed at each of two levels along the nerve and a section of the nerve is excised. Care must be taken not to tear any of the many small veins and the possibility of anomalous arteries should be kept in mind. The peritoneum is permitted to fall back into place and the rectus fascia and skin sutured. No cast or apparatus is employed. In a consecutive series of resections of seventy-four nerves by this method, no complications of any nature have developed. The relaxation of the adductor group in this manner is more satisfactory than other methods we have employed. In no case have we had abduction deformities develop. Some adduction persists

due to secondary innervation from the sciatic nerve

Flexion deformity of or inability to extend the knee completely is next in importance. Here again, stretching is of only temporary benefit and more radical measures are justifiable. Lengthening of the hamstring muscles, stripping of the posterior capsule, supra condylar osteotomy or neurectomy of the hamstring branches of the sciatic nerve may relieve the active deforming factor in properly selected cases. Too frequently, however, complete active extension with or without weightbearing is lacking even though passive extension of the knee is possible. In many of these cases an abnormally high position of the patella is found. This observation was recorded and a corrective operation outlined in a paper entitled, "Re-establishment of Normal Leverage of the Patella in Knee Flexion Deformity in Spastic Paralysis," which was published in 1933. In order to lower the patella to a position at the level of the knee joint, the insertion of the patellar tendon is transplanted distally on the anterior aspect of the tibia. In some cases in which the spasm of the quadriceps is especially pronounced, difficulty in maintaining the reinsertion has been encountered. Several valuable suggestions have been made to improve the original technique. Carrell encircles the patella with wire which is fixed to the tibia. Burns transfixes the patella with a Kirschner wire and fixes it in the cast so as to aid in maintaining advancement. Many other possible variations of technique are obvious. The possibility of arrested growth of the anterior portion of the upper tibial epiphysis must not be overlooked. This is especially true if this operation is undertaken in young children. A plastic operation on the patellar tendon will accomplish advancement more safely. Cleveland, Wagner Speed and many others have reported successful results with the basic principle of patellar advancement.

Transplantation of the biceps tendon to the patella has been practiced widely but this should supplement patellar advancement to give the best results. Equinus

deformity of the foot comes next in importance in the consideration of spastic disabilities of the lower extremities. The relation of this deformity to the stabilization of the knee must be kept in mind. Lengthening of the tendo Achilles results in good correction in many cases but in others greater disability. Resection of the motor branches of the popliteal nerve is also effective but difficulty is encountered in estimating the degree of neurectomy.

A fixed equinus deformity is frequently observed when the knee is held extended although a satisfactory dorsiflexion is obtained when the knee is flexed. This indicates a contracture of the gastrocnemius portion of the calf rather than of the entire calf group. Sherb recognized this fact and in 1935 published a paper describing an operation of multiple fasciotomies of the fascia of the gastrocnemius muscle. This procedure has been called the herringbone fasciotomy because of the alternating incisions used in lengthening this fascia. The large amount of muscle tissue in the soleus renders it more amenable to stretching as compared with the gastrocnemius.

H. A. Durham recently reported a simple but effective operation to correct internal rotation of the thigh. In this the anterior portion of the gluteus medius is divided at its insertion into the greater trochanter. A cast holding the legs externally rotated is employed postoperatively. Instability of the foot presents a greatly varied problem and methods of correction should be adapted to each individual deformity. In our experience, tendon transplant alone does not prove as satisfactory as when combined with arthrodesis of the posterior tarsus. In equinovarus deformity, lengthening of the posterior tibial tendon is helpful. Reinsertion of the anterior tibial tendon into the dorsum of the tarsus has given good results in a small number of cases. Overactivity of the peroneus longus muscle with valgus deformity of the forefoot responds favorably to lengthening of the peroneal tendon combined with a medial cuneiform osteotomy which includes the

scapho-cuneiform joint The relation of adductor spasm of the hip to this particular deformity bears re-emphasis

Correction of extension deformities of the toes should not be attempted until the tarsus itself is properly corrected Insertion of the long toe extensors into the metatarsals is the procedure of choice Arthrodesis of the interphalangeal joint of the first toe is done to prevent hammer-toe deformity

Disability due to spastic paralysis of the upper extremity resists correction to a much greater degree than that of the lower This is probably due to the finer movements which normal function implies as well as the greater degree of non-use that occurs in the upper extremity in the presence of any malfunction Pronation of the forearm associated with flexion of the wrist is usually the outstanding deformity

Treatment of this condition by constant stretching and splinting is discouraging and surgical measures are justifiable An understanding of the interrelationship of these deformities is essential An attempt at correction of the pronation of the forearm without correction of the wrist deformity invites failure, for the flexed wrist and dependent hand act to pronate the forearm when the patient is in the upright position, thereby offsetting the benefits of any correction that may have been accomplished Correction of flexion deformity of the wrist is therefore the key to this complex disability This may be accomplished by transplantation of the carpal flexors to the extensors or better, especially in older patients, by arthrodesis of the radio-carpal articulation holding the hand in fifteen to twenty degrees of extension Due to the presence of motion between the carpal bones, wrist fusion alone is only partially successful To obviate this factor, we have used a heavy cortical graft inserted subperiosteally on the dorsum of the radius, bridging the wrist-joint and fixed in a deep cleft in both rows of carpal bones, at times reaching to the metacarpals This graft is effective in immobilizing the wrist as well as the car-

pus, itself The function of the fingers is greatly enhanced by the improved position of the wrist With the wrist in good position, correction of the pronation may be accomplished by division of the pronator teres and pronator quadratus, or possibly by converting the pronator teres into a supinator (Tubby operation) Our results in section of the branches of the median nerve have been uniformly poor

We have had little occasion to employ the thumb-check operation or alter the function of the finger flexors by tendon lengthening Deformities of the shoulder and elbow rarely necessitate surgical intervention

In spastic paraplegia resulting from permanent cord damage of acquired nature, similar surgical procedures have been employed The extraperitoneal obturator and popliteal neurectomies are most useful The sensory and trophic changes which accompany these types of pathology limit the scope of surgery considerably

Choreoathetosis is probably the most distressing clinical entity met in dealing with spastic paralysis in the wider meaning of the term These patients, who are of more normal mentality than are those of Little's disease, present an ever varying picture of irregular muscular control involving a single extremity or all of the body Distortion of function of the facial muscles associated with attempts of speech are especially distressing No consistency of disability is present and, therefore, most usual surgical procedures are of little or no avail Intensive physical therapy carried out along the usual line of repeated exercises intensifies the condition rather than improves it A large variety of drugs have been employed in treatment without distinct results Occasionally improvement in gait follows stabilization of the feet This is due to the lessening of effort in the maintenance of balance and the relative simplification of pattern of nerve stimuli The bizarre ineffective movements are best explained by altered stimuli arising in the basal nuclei, especially Deiters' nucleus and the red nucleus as well as in Corpus striatum

The majority of these efferent stimuli pass along the rubrospinal tract which lies deep in the anterolateral portion of the cord. Putnam approached this problem by dividing the rubrospinal tract by anterolateral cordotomy. His results were encouraging. Stimulated by his report, we selected seven cases of choreoathetosis for a trial of this procedure. Dr. Eric Oldberg performed cordotomies high in the cervical cords of these patients with definite but limited improvement in all cases. I have followed these cases to date and feel that the procedure fully justifies the risks involved. This type of surgery should be done by a well trained neurosurgeon rather than by one whose training has been in orthopedic surgery.

Conclusions

- 1 The surgical treatment of spastic paralysis has been presented in an attempt to evaluate the procedures most useful in bringing relief to a large group of unfortunate individuals.
- 2 The need of continuation of less radical means of therapy is recognized.

Discussion

Dr. Mather Cleveland, *New York City*—We are indebted to Dr. Chandler for a reprintment of Little's classic description of the disease which so frequently bears his name.

In describing the underlying pathology of spastic paralysis a proper emphasis is placed on the loss of inhibitory action of the upper motor neurone. The actions of these patients are neither purposeful nor effective.

Dr. Chandler is quite correct in suggesting that a better title would be *Surgical Phases in the Treatment of Spastic Paralysis*. Surgery is only a small part of the picture. There is unfortunately as yet no treatment surgical or medical which is successful in combating the underlying pathology.

My conception of the use of surgery on these patients is that it is an attempt to make it easier for the spastic to bear his burden.

At St. Luke's Hospital surgical intervention in spastic paralysis has been confined largely to the lower extremities in an effort to overcome deformities and restore balance at the hips, knees and feet.

To overcome adductor spasm or scissors gait we have usually divided the adductor longus and

brevis and divided the anterior division of the obturator nerve. This has been inadequate. I am very much interested in Dr. Chandler's approach for bilateral complete division of the obturator nerves. I can only wonder if it is not too final a step to take before trying the effect of partial division.

The advancement of the patella as described by Chandler has in our hands been a very successful procedure. It takes the spastic out of the jump position and improves his gait. There is usually a slight tendency for the knee flexion to recur and this happens because a little knee flexion and adduction is at times necessary to enable the spastic to balance himself. With completely straight knees and wide stance he may fall or totter badly.

In some of these badly flexed knees we have had to precede the advancement of the patella by posterior capsulotomy of the knee joints and by injection of the nerves to the hamstrings with absolute alcohol or at times by partial resection of these nerves.

The foot deformities of equinovarus or equinovaglus are best controlled by subastragaloid arthrodesis and posterior malleol block. Lengthening of the heel cords is a procedure with some risk as it may increase knee flexion deformity. We have at times paralyzed the calf muscles temporarily by alcohol injection of the nerves.

Our experience with surgical intervention on the spastic deformities of the upper extremity is limited. Here stability is no longer required but rather a fine co-ordination of movement is needed which the underlying spastic condition defeats. We have occasionally fused in dorsiflexion a badly flexed wrist joint to allow the hand and fingers to grasp. This is only worth while if there is fairly good motor control at shoulder and elbow.

Dr. Chandler has wisely emphasized the fact that surgical intervention is but a small part in the training of spastics. Endless patience is required to educate them to use their muscles so they may assume as nearly a normal role in the community as possible.

Dr. Lewis Clark Wagner, *New York City*—I am very much impressed with Dr. Chandler's statement that operation can be considered only as a step in the treatment of spastic paralysis. Education—mental, physical and moral—is the first and most important step in the rehabilitation of those affected with this type of disease. A great deal more research must be done on the etiology of spastic paralysis and I sometimes wonder whether it should be classed as a birth injury exclusively. I have had the opportunity to observe this disease in twins delivered by

caesarian section. Certainly, the changes in the central nervous system must have antedated the birth of the children.

Dr. Thibodeau, Dr. Carr, and I have reviewed 554 operations for the relief of deformities of patients affected with spastic paralysis, and we have been surprised at the figures of the failures in standardized procedures. Briefly, operations for stretchings of the deformities of spastic paralysis were 90 per cent failures. Lengthening of the tendo Achilles resulted in 68 per cent failures because of recurrence of the deformity. Resections of the nerve to the gastrocnemius without contraction of the muscular groups were 70 per cent successful. In the groups where contractures of the gastrocnemius group were noted, lengthening of the tendo Achilles and resection of the nerves to the gastrocnemius group were pretty nearly always successful.

I agree with Dr. Chandler that bony operations associated with tendon transplantation about the foot give the best results. The posterior bone block which he has not mentioned for spastic equinus in the older individuals has been very satisfactory in our hands. Dr. Chandler's operation for advancement of the patellar tendon deserves special mention and, after correction of the flexion deformity by manipulation or osteotomy of the femur, it is the operation of choice for restoration of normal leverage of the knee.

My statistics of the operations performed during the period from 1926 to 1937 show seven cases of this type, all with good results, and I am sure that in the last year, we have augmented

this series by many other successful cases. I can recommend the operation wholeheartedly and know that the number of biceps femoris transplantations will be greatly lessened in the future because of the use of this operation. I have had no experience with the "herring bone fasciotomy," but I welcome any procedure that can be done without the necessity of lengthening the tendo Achilles.

I have not performed the intra-abdominal neurectomy of the obturator nerve, as I have been content with the old method of Stoffel, but I hope to try it in the future. Once the technique is mastered, I am sure it will prove very simple. Operations on the spinal cord in our series have not been successful enough to warrant the procedure, as the paralyses resulting from section of the spinal tracts have been worse than the athetoid manifestations. Sympathetic ramus section or a ganglionectomy is mentioned only to be condemned. Our eight cases, two performed by Royle himself, showed all to be failures.

In conclusion, the surgical treatment of spastic paralysis should not be the correction of deformity so much in the greater part, but the removal of the separate offending obstacles which produce the retardation of function to an individual part. We cannot expect to make these afflicted persons perfect, to "leap as a hart," as the saying goes, but we can help a great many to be useful citizens by removing obstructions to locomotion and function. By removing these obstacles, greater attention can be given to the re-education with associated relief of spasticity, which is most desired.

FACING PEONAGE

The fighting line against major epidemics in this country has been the body of physicians in private practice.

They have been the infantry in the army of health preservation and restoration. They have battled at the bedside while politicians organized such manifest futilities as shotgun quarantines, and subjected traveling families to inhuman hardships.

It is this body of veterans of thousands of battles against death and disease who are today threatened with the degradation of their profession on one hand and gathering economic difficulties on the other.

It is this group of devoted men who face that peonage into which government has already forced the far too large labor surplusage, and is seeking now to constrain the professions.

Are you and I going to let the doctors fight alone, or are we going to tell our Assemblymen and Senators to follow the recommendations of the Medical Society of the State of New York?

You have a vital concern. Do you want to be your family doctor's patient, or case No. 17521?—John A. Heffernan, in the *Brooklyn Eagle*.

TREATMENT OF PNEUMOCOCCUS III PNEUMONIA WITH RABBIT SERUM AND SULFANILAMIDE

ROBERT T. GARRETT, M.D., Southampton, and JOHN RUSSELL TWISS, M.D., New York City

(From the Department of Medicine of the New York Post Graduate Hospital)

THE treatment of pneumococcus III pneumonia is of great practical importance because of its prevalence, high mortality, and the resistance of bacteremic cases to our present horse serum. In view of this fact there is urgent need of further study of specific methods of treatment. As a contribution to this investigation we are here reporting a series of 8 cases of pneumococcus III pneumonia treated by specific rabbit serum and sulfanilamide. Of the 4 cases treated with rabbit serum, 1 with bacteremia, all recovered. Of those treated with sulfanilamide, there were two recoveries, one failure to respond to treatment, and one death.

The history of pneumococcus III (formerly called streptococcus mucosus) begins with its classification by Dochez and Avery¹ in 1913. A review of cases reported in the literature shows certain clinical characteristics of pneumococcus III pneumonia which are of interest. Bullowa² found this type to be exceeded in prevalence only by Type I pneumococcus pneumonia. Finland and Sutliff³ report an incidence of bronchopneumonia of 21 per cent in pneumococcus III pneumonia in contradistinction to 3 to 5 per cent incidence in Types I and II.

Pneumococcus III pneumonias occur quite commonly in the aged. Cecil, Plummer, and McCall⁴ have reported 65 per cent of their patients with pneumococcus III pneumonia over the age of 40. Cecil, Baldwin, and Larsen⁵ found that 34 per cent of all their pneumonias in patients over the age of 60 were caused by the pneumococcus III organism, this incidence being about twice that of Types I and II. All of these investigators have stressed the importance of predisposing factors such as age, debility, chronic alcoholism, and cardiovascular disease.

Seasonal variations are striking, most of the cases occur between December and March.

The onset of pneumococcus III pneumonia is variable. According to Bullowa² the characteristic symptoms of the lobar type are the abrupt onset, frequently with chills, fever, pain in the side, cough, or rusty sputum. Finland and Sutliff³ however, state that with bronchopneumonia the onset is frequently gradual and there may be none of the characteristic symptoms. Both types are apt to terminate by lysis, the average duration of fever being nine days. The average stay in the hospital is reported by Millett⁶ as being twenty-two to twenty-three days.

The average mortality in pneumococcus III pneumonia is high, the rate of 40 to 60 per cent in various groups^{2,3,4} being exceeded only by Type II pneumonia. Advanced age and chronic disease are conceded to be a factor in this high mortality. Cecil, Plummer, and McCall⁴ reported that in pneumococcus III pneumonia the mortality rate in chronic alcoholics was 50 per cent, in patients with cardiovascular disease, 77 per cent. Most important, however, seems to be the bacteremia which occurs in about one third of the patients. Finland and Sutliff³ reported a 100 per cent mortality in 46 cases of bacteremia. Blake⁷ reports one recovery in 21 cases. Bullowa's² series showed a mortality of 96 per cent. Cecil, Baldwin, and Larsen⁵ gave the average mortality as being approximately 90 per cent.

The previous specific methods of treatment of pneumococcus III pneumonia have proved almost uniformly unsatisfactory. The ineffectiveness of horse serum has been mentioned. Among the methods of treatment tried without results are pneumococcus vaccine, convalescent

serum, Huntoons pneumococcus antibody serum, and Felton's concentrated serum. The use of donors immunized with pneumococcus vaccine was tried in 6 cases by Barach,⁸ who reported no apparent effect from this treatment, his 4 cases of bacteremia all resulting fatally. The primary problem as stated by Cecil,⁴ et al is the stimulation of a high titer of immune bodies by the injection of killed or living Type III pneumococci.

In approaching the problem of making a satisfactory antipneumococcus serum, Horsfall, Goodner, MacLeod, and Harris⁹ claim that there are certain disadvantages in using horses for this purpose, such as their expense, the uncertainty of producing a potent serum, the limited serum strength, the anaphylactic reactions which so frequently follow the use of horse serum, and the subsequent serum sickness. They therefore made a refined rabbit serum, which they considered less subject to these objections, by the repeated intravenous injections of pneumococci, filtering the serum and absorbing with sterile washed kaolin.

Among the advantages of rabbit serum over horse serum, as stated by Horsfall⁹ and his associates, are the smaller size of the antibody (which allows the greater penetration into tissues) and the concentration which they obtained of 2,000 units per cc. Practically all rabbits inoculated produced potent serum, the cost for equivalent amounts of antibody being therefore less than that of horse serum. Little or no reaction was said to result from the use of this serum in 22 patients with lobar pneumonia of Types I, II, VII, and VIII. Recovery from the pneumonia occurred in all cases, notwithstanding the presence of bacteremia in 12 patients.

Studies on the immunity of the rabbit to pneumococcus III pneumonia infections have been made by Tillett,¹⁰ who explains the failure of horse serum in treatment as being due either to the inagglutinability of the organisms having a mucoid capsule or to the absence of agglutinins in the serum. Tillett,¹⁰ however, found that the injection of pneumococcus III

antigen into a series of rabbits failed to produce specific agglutinins in 86 per cent. Further studies, however, showed that the intravenous injection of large doses of encapsulated pneumococcus III organisms failed in most cases to kill rabbits, which Tillett¹⁰ explained as being due to antibody action destroying the protective capsules. Active immunization against virulent strains of the encapsulated pneumococcus III was finally accomplished in rabbits by the repeated injections of heat-killed cultures of pneumococci. An excellent discussion of the use of rabbit serum has been published by Bullowa.²

Through the kindness of Dr Jesse G M Bullowa we were able to obtain Type III antipneumococcus rabbit serum¹¹ for treatment in 4 critical cases of pneumococcus III pneumonia at the New York Post Graduate Hospital. A skin test was found to be negative in each case. Owing to a severe degree of shock which followed a single intravenous injection (which we are given to understand does not occur with the purified product now available), all serum was given intramuscularly. No reactions of any consequence occurred after the intramuscular injections. The dosage varied from 80,000 to 104,000 units, the serum being started on the second, third, and sixth days of illness.

Case Reports

Case 1—V L, female, age 60, was admitted with a history of four days' duration of chills, fever, cough, hemotysis, nausea, and vomiting. Previous history of asthma, pneumonia three years before admission. The initial physical examination showed the patient to be extremely toxic and irrational, temperature 102 F, pulse 110. Signs of dullness and diminished breath sounds of the right lower lobe. The x-ray diagnosis (by Dr William H Meyer) was a bronchopneumonic infiltration of right lower lobe. Sputum showed pneumococcus III. Blood cultures were reported by Dr Adele Sheplar to be negative. Blood count: leucocytes 13,000, polymorphonuclears 89 per cent. Urinalysis: numerous granular casts. Blood chemistry: normal. Beginning the sixth day, antipneumococcus Type III was given, 15 to 20 cc every three hours intramuscularly. A total of 80,000 units were given in twenty-four hours. A severe chill followed the

first dose of 15 cc. but not subsequent injections. The clinical condition of the patient after twenty-four hours of serum treatment was improved; the temperature and pulse fell gradually to normal over a period of four days. The succeeding course was essentially uneventful; the patient being discharged thirty-two days after admission.

Case 2—A.W. male age 61 was admitted with a history of two days' duration of pain in the chest, malaise, cough, chills and fever. Dyspnea on day of admission. Previous history of cardiac disease probably arteriosclerotic. Physical examination showed an acutely ill patient with respiratory distress, having dullness diminished breath sounds, bronchial breathing and scattered moist rales mostly in the right lower chest posteriorly. X-ray studies later showed a diffuse bronchial infiltration of both central lung fields, with lobar consolidation of the right lower lobe, where there was concomitant pleural thickening. Sputum examinations taken on admission showed Type III pneumococci; blood culture was negative. Blood count showed 30,800 white blood cells, polymorphonuclears 95 per cent.

The skin tests and dilute serum intravenously giving no reactions. 5 cc. of Type III rabbit serum was given intravenously. Twenty minutes later the patient developed a severe chill with a temperature of 104.5 F. became cyanotic and cold; pulse rate about 100; radial pulse almost imperceptible. Blood pressure dropped from 96/60 to 50/30. While the patient was in shock, auricular fibrillation developed (as proved by the electrocardiogram). The patient gradually responded to shock treatment and large doses of digitals; the fibrillation stopped and there was definite clinical improvement on the second day. The blood culture at this time showed pneumococcus III (Dr. Sheplar). At this time there was an elevation in the temperature to 103 F., pulse rate being 110. Upon the recommendation of Dr. Bullock, who saw the patient in consultation, Type III rabbit serum was given intramuscularly in doses of 10 to 30 cc. After 40,000 units had been given there was clinical improvement, the blood culture was at this time sterile. The subsequent clinical course of the patient was characterized by extreme toxemia and abdominal distention, hiccoughs, intermittent fibrillation and heart block. The temperature fell by lysis, becoming normal two days after the cessation of serum treatment. The subsequent course was again uneventful; the patient being discharged on the twenty-seventh hospital day in good condition.

Case 3—M.D. female, age 43 was admitted October 4 1937 for a radical left mastectomy

which was performed by Dr. John F. Erdmann. The patient had had three attacks of pneumonia in the ten years previous to admission. The day following operation the patient developed chills and fever of 105 F., pulse was 130, respirations 40. There were definite signs of consolidation by x-ray. Sputum examination showed a pneumococcus III; blood culture was sterile. Leucocytes were 12,000, polymorphonuclears 95 per cent. The patient was placed immediately in an oxygen tent where she remained for six days. Sulfanilamide was given, 80 grains the first day, 70 grains the second, with no appreciable effect upon the temperature, pulse, or respiration. The patient was restless, delirious, and cyanotic during this period. Rabbit serum was begun the third day, the skin test being negative. The serum was given entirely intramuscularly, an initial dose of 1/2 cc. being doubled every forty minutes until a maximum of 55 cc. was given. The total dosage of serum was 104,000 units. During six hours after completing the serum, the patient began to improve, having less respiratory distress; the temperature dropping to 102 F., the pulse rate decreasing from a rate of 140 to 120. The temperature again went to 104 F. twenty-four hours later but gradually fell by lysis, returning to normal in eleven days. The patient was discharged eighteen days after the onset of the pneumonia.

Case 4—M.S. male, age 43 was admitted January 26 1938, and was seen in consultation with Dr. Charles Polindexter. There was a history of indigestion and intermittent attacks of colic in the right upper quadrant of six weeks duration. Past history of migraine. Type II pneumococcus pneumonia four years before admission. Physical examination showed some tenderness in the right upper quadrant; temperature was 99.5 F., pulse rate 90, respirations 22. Leucocytes were 11,600, polymorphonuclears 55 per cent. A diagnosis of acute cholecystitis was made and an inflamed edematous gallbladder and a diseased appendix were removed by Dr. John F. Erdmann. A cough developed ten hours after operation; examination at this time showing diminished breath sounds in the right base posteriorly with a small area of bronchial breath sounds. The temperature was 101.5 F., pulse rate 120, respirations 40. Sputum examination showed pneumococcus III; blood cultures were sterile. The intradermal test being negative 1/2 cc. of rabbit serum was given intramuscularly, doubling the dose every forty minutes. A total of 92,000 units were given in five hours without reaction. The temperature began to fall twelve hours after beginning the serum; the temperature becoming normal the fifth postoperative day.

WHILE the use of sulfanilamide in the treatment of pneumococcus III pneumonia has been extensively discussed, there are few reports of results following this method of treatment. Heintzelman, Hadley, and Mellon¹² call attention to the high incidence of lobar and influenzal pneumococcus III pneumonias in eastern cities during 1937 and report 9 cases of this character treated by sulfanilamide. Of the 11 cases treated, 1 with bacteremia and 1 without bacteremia died, giving a mortality of 18 per cent. In a control series of 12 untreated cases, 2 with bacteremia and 8 without bacteremia died, giving a mortality of 83 per cent. The same authors quote Robinson of the Allegheny General Hospital, whose 7 cases of pneumococcus III pneumonias with bacteremia all died. Millett⁶ has reported 1 case of pneumococcus III pneumonia recovering following the use of sulfanilamide.

The 4 cases of pneumococcus III pneumonia here presented had in each case a negative blood culture and were treated with sulfanilamide by mouth, supplemented in several instances by Prontylin given intramuscularly. The first case was relatively mild and was treated promptly, making a good recovery. Two patients having indefinite and atypical symptoms making a differential diagnosis difficult were treated on the second and third days of their illness, one recovering and a woman of 53 dying on the seventh day of her illness. The fourth case was treated for forty-eight hours with sulfanilamide, which was then discontinued in favor of rabbit serum because of the critical condition of the patient and her complete lack of response to sulfanilamide.

Case 1 —L M, male, age 60, was seen outside in consultation with Dr Peter Irving in April, 1937. Chills and prostration twenty-four hours before admission were followed by a productive cough and sense of oppression in the chest. Physical examination showed diminished breath sounds in the left base, where x-ray showed a bronchopneumonic consolidation. Blood culture was negative. Leucocytes were 6,800, polymorphonuclears 74 per cent. Sulfanilamide 10

grains were given by mouth every four hours for forty-eight hours, 20 cc of Prontylin being given twice hypodermically the first day, 10 cc three times the second day. Within twelve hours there was a drop in temperature from 104.6 F to 99 F, the pulse rate being reduced from 108 to 84. The sulfanilamide was continued for a week, 10 grains three times daily. The temperature remained relatively low for three days, becoming, however, 103 F the seventh day. After this there was a fall by lysis, the temperature becoming normal on the nineteenth hospital day. At the end of the first week of treatment it became evident that the patient was unable to empty his bladder and that obstruction with overflow was present. This was due to a prostatic hypertrophy, without infection, for which a prostatectomy was later successfully performed.

Case 2 —H B, male, age 32, was admitted on the Surgical Service, November 2, 1937, seen by courtesy of Dr Reynold Church. There was a history of epigastric pain of thirty hours duration, associated with chills, fever, nausea, vomiting, and faintness, no cough. Physical examination showed an acutely ill male with normal lung resonance, scattered moist râles of the right base, and generalized abdominal tenderness which was most marked in the right lower quadrant. A diagnosis of acute appendicitis with bronchitis was made, followed by an appendectomy under spinal anesthesia.

The day following operation the patient became cyanotic and perspired freely, a cough being associated with hemoptysis. Sputum examination showed pneumococcus III, the blood culture was sterile. The x-ray showed a bronchopneumonic infiltration of the right lower lobe. The patient was given 15 grains of sulfanilamide every four hours, 1 ampule of Prontysil intramuscularly three times daily. Oxygen was given by nasal catheter the first day. After thirty-six hours of sulfanilamide treatment there was clinical improvement, with reduction in the fever, pulse, and respiratory rate. The dosage of sulfanilamide was gradually reduced. The temperature became normal in the tenth day after admission and the patient was discharged in good condition on the seventeenth day.

Case 3 —S C, female, age 53, was admitted on the Surgical Service, November 20, 1937, with a history of pain in the right upper quadrant, with nausea, vomiting, and fever, of one day's duration. The tentative diagnosis was empyema of the gallbladder, the physical examination revealing no chest signs but tenderness and spasm in the right upper quadrant. The leucocyte count was

15 000 polymorphonuclears 88 per cent On the third day of her illness the patient developed a respiratory rate of 30 per minute, cyanosis and cough. There was dullness with diminished breath sounds in the right base the x ray showing a consolidation of the right middle lobe with intralobular involvement Sputum typing showed the infection to be due to pneumococcus III Blood culture was sterile

The patient having on the third day a temperature of 103 F and a pulse of 120 with cyanosis and labored respirations, was put into an oxygen tent. Since the tablets of sulfanilamide were refused 30 grains of sulfanilamide were given in a clysis the first day Prontysil was also given intramuscularly 40 cc the first day 60 cc. the second The second and third days 60 grains of sulfanilamide were given, dissolved in clyses. During this period the polymorphonuclear cells dropped from 4 to 3.5 million the hemoglobin from 80 per cent to 70 per cent the leucocytes rose from 11 600 to 28 000 The blood culture was sterile. The condition of the patient became progressively worse her coma and toxemia increasing notwithstanding the treatment Her death occurred seven days after the onset of pneumonic symptoms.

Case 4—M.D. female age 43, is discussed under Case 3 treated by rabbit serum The patient previously described as toxic and critically ill was treated in an oxygen tent for two days being given 80 grains of sulfanilamide the first day and 70 grains the second day The blood culture was sterile. There being no apparent effect clinically or upon the temperature, pulse or respirations, the sulfanilamide was stopped and rabbit serum begun on the third day About twenty-four hours after the beginning the rabbit serum the patient began to show clinical improvement, making eventually an uneventful recovery

Discussion

Pneumococcus III pneumonia is one of the most common and most frequently fatal types. It is common in the aged and in those with chronic disease The incidence of bronchopneumonia is usually high, up to a fifth of the reported cases showing no lobar consolidation The mortality in the nonbacteremia cases is about 40 per cent, with bacteremia the estimated average mortality is 96 per cent.

Although conclusions cannot be drawn from a limited number of cases, 4 patients (1 with bacteremia) are here reported who

recovered following the intramuscular use of relatively small doses of rabbit serum, 80,000 to 104,000 units Most investigators, however, favor larger doses by the intravenous route, as explained by Bullowa in his *Management of the Pneumonias*²

A further series of 4 cases of pneumococcus III pneumonia is presented which were treated with sulfanilamide. Two of these patients recovered One patient treated with sulfanilamide without apparent effect for a period of forty-eight hours finally recovered following the use of rabbit serum One patient who refused medication by mouth became progressively worse and died notwithstanding the use of Prontysil intramuscularly and sulfanilamide by clysis

The impressions gained by these studies were that pneumococcus III rabbit serum given intramuscularly had a beneficial effect upon 4 patients who were extremely toxic and critically ill Sulfanilamide given under the same circumstances showed no apparent effect in 2 cases, in 2 others less severe improvement followed its use. Our limited experience with this drug would seem to indicate that if no response occurs within forty-eight hours of treatment the sulfanilamide should be discontinued

Since the onset of the disease in most of the patients here presented was atypical having no really diagnostic symptoms or findings in some cases until the third or fourth day of their illness, the importance of considering pneumonia in differential diagnosis is stressed All suspicious cases of this character should be in our opinion hospitalized and have sputum typing and blood cultures done, as well as having an x ray of the chest.

NEW YORK CITY DEPARTMENT OF HEALTH

The Bureau of Social Hygiene of the Department of Health, New York City, announces Part One of a course in "Social Hygiene." It is offered to physicians and other interested persons as part of the educational efforts in modern syphilis and venereal disease control.

Lectures, which were started February 4, are given on Saturday mornings, at 10 30 in the Department of Health Building, 125 Worth Street, Conference Room, second floor. Each lecture is repeated on the following Tuesday afternoon, at 4 00 at 130 Leonard Street (Department of Health Building), clinic waiting room. Two opportunities to hear each lecture are offered.

The seminar will include discussions of the history of syphilis, the past and contemporary venereal disease control programs. Emphasis will be on public health, laboratory diagnosis, clinical interpretation of syphilis, and nonsyphilitic venereal diseases.

Stress will be laid on the importance in the modern control effort of the physician, epidemiologist, social worker, nurse, and investigator.

Lantern slides and motion pictures will be

shown and literature distributed. Free discussion from the floor will be encouraged.

PART ONE

Department of Health Aspects of Syphilis, by Dr Theodore Rosenthal was given on Feb 4 and 7. Mythology and History of Syphilis (to 20th Century), by A. A. Brown, Jr., was given on Feb 11 and 14.

Below is the schedule for the remaining lectures of Part One. Feb 18 and 21. Modern History and Present Needs, by Dr Herman Goodman. Feb 25 and 28. Cause and Epidemiology, by Dr Daniel F. Crowley. Mar 4 and 7. Symptomatology and Dangerous Lesions, by Dr Louis Chargin. Mar 11 and 14. Syphilis in Pregnancy, Family Consequences, Early Congenital Syphilis, by Dr Margaret Davis. Mar 18 and 21. Congenital Syphilis. Late Disabling Permanent Changes, by Dr Nathan Sobel. Mar 25 and 28. The Burden of Syphilis on Society, Cost of Medical Care, Direct and Indirect, by Mr Philip S. Broughton.

Subjects and speakers for Part Two will be announced early in March.

PNEUMONIA INSTITUTE PLANNED FOR TROY

The Medical Society of the County of Rensselaer, in collaboration with the New York State Medical Society, the State Department of Health, and one of the hospitals in Troy, will sponsor a graduate institute for physicians on the "Diagnosis and Treatment of Pneumonia," to be held March 2.

A full day will be devoted to the clinical and therapeutic aspects of pneumonia. Lectures on the early symptoms and signs, bacteriologic diagnosis, serum, and chemotherapy will be

given by nationally known authorities on the subject. Practical demonstrations of the technique of serum administration and oxygen therapy will be given. Ample time will be allowed for questions and discussion.

Physicians in counties adjacent to Rensselaer are invited to attend. Applications should go at once to the Chairman of the Public Health Committee of the Rensselaer County Medical Society, Troy, New York. Registration will close February 23.

The British Medical Association is forming a central medical film library to lend films for local meetings. Practitioners who have made films

of medical interest have been asked to contribute copies to the library, which is expected to prove of great value to the profession.

THE ECONOMIC STATUS OF PATIENTS ADMITTED TO TUBERCULOSIS CLINICS OF THE NEW YORK CITY DEPARTMENT OF HEALTH

H. R. EDWARDS, M D, *Director of the Bureau of Tuberculosis*

HAZEL D. CONNELL, *Secretary Tuberculosis Records*

THE continued expansion of clinic services within recent years in New York City has caused some alarm among physicians engaged in the private practice of medicine. There has been criticism to the effect that free clinics are accepting for diagnosis and supervision many patients able to pay for such services under private medical care. Recently medical societies have attempted to set up certain standards of income as a basis for admission to free or pay clinics and to establish standards for fees charged by clinics. Consequently, it is important to make available information concerning the economic status of cases admitted to the tuberculosis clinics of the New York City Department of Health. This paper, therefore, sets forth the results of a careful study of the income status of a representative sample of clinic patients.

Tuberculosis Clinics in New York City

Preliminary to the discussion of income status, it seems suitable to give a brief description of the clinics. The Department of Health operates twenty-two tuberculosis clinic stations in the five boroughs. In these stations three distinct services are rendered, all of which are entirely free. They are (1) diagnostic, (2) consultation, and (3) pneumothorax. All of these services are open to any resident of the City of New York regardless of income, in accordance with statutes of the State of New York for the control of communicable diseases.

The purpose of the diagnostic clinic is to examine for tuberculosis anyone who applies for examination, to arrange suitable care for those in need, and to examine and supervise contacts of diagnosed cases over a period sufficient to assure their

ultimate safety. These clinics supervise also the ex sanatorium case discharged for ambulant care.

There are nine consultation clinics, and their purpose is to render chest consultation service to private physicians who have cases unable to pay for x rays or to pay standard fees charged by chest specialists. This service is free both to the patient and to the physician. The work of two of these clinics has been recently reported in the literature.^{1,2}

There are six pneumothorax services operated in selected clinics in the city. They are for the supervision of ambulant pneumothorax cases discharged from the various city hospitals.*

However, the Department of Health does not render all tuberculosis service in the city. The city is subdivided into Health Center Districts which comprise approximately 250,000 to 300,000 population each. In general, tuberculosis services are set up to conform to these districts. In some districts the routine diagnostic and pneumothorax services are available in the outpatient services of public or private hospitals. The combined services as indicated in the above three categories (diagnostic, consultation, and pneumothorax) total sixty-two for the city. Thirty-six, or 58 per cent, are under the Department of Health, fourteen or 23 per cent, are under the Department of Hospitals, and twelve, or 19 per cent, are under private hospitals or agencies.

The percentage varies according to type of service. Thus, the Department of Health operates 80 per cent of the diagnostic, 90 per cent of the consultation, and 31 per cent of pneumothorax

* Initial pneumothorax is not attempted in any of these clinics.

TABLE 1 DISTRIBUTION OF FAMILIES STUDIED FOR ECONOMIC STATUS IN THE VARIOUS BOROUGHES OF NEW YORK CONTRASTED WITH THE TOTAL ADMISSIONS TO CLINICS—JULY-DECEMBER, 1936

| BOROUGHES | SAMPLE STUDIED | TOTAL ADMISSIONS TO CLINICS, JULY-DECEMBER, 1936 | |
|----------------|----------------|--|--|
| | | Percentage | |
| Total New York | 100 1 | 100 0 | |
| Manhattan* | 22 6 | 30 7 | |
| Bronx | 14 3 | 14 8 | |
| Brooklyn | 45 0 | 39 8 | |
| Queens | 15 5 | 12 2 | |
| Richmond | 2 7 | 2 5 | |

* Excluding New York Hospital Vanderbilt and Meinhard Clinics. The New York Hospital and Vanderbilt Clinics are supported in part by Department funds and serve designated districts. They are not included in this study because the returns were not as complete as in those clinics completely under our control. At the time of this study Meinhard Clinic was used as a survey station for families on home relief. It is believed that the income status in these clinics do not vary from the findings in our regular clinics.

In the latter clinics we carry approximately 45 per cent of the ambulant clinic case load.

Income Status of Patients Admitted to Diagnostic Clinics and Pneumothorax Service

This study of income status of clinic patients consists of records for 5,963 individuals admitted to the diagnostic clinics and 280 individuals admitted to the pneumothorax services during the latter half of the year 1936. Each new case admitted was interviewed by the nurse in order to determine the source and amount of the total income from all wage-earners in the family at that time. A record of the number of individuals in the family was also secured from the patient so that income might be considered in relation to size of family. The data were carefully reviewed for uniformity and completeness of recording.

Diagnostic Clinics—It is believed that the sample described above is representative of the Department of Health Clinics for the city as a whole. Table 1, above, shows for the sample drawn from the diagnostic clinics the proportion of persons from each borough compared with the distribution of total admissions to clinics by borough. The sample contains a slightly higher proportion of persons from Brooklyn clinics and fewer from Manhattan clinics than does the propor-

tion of total admissions shown. However, the sample described in this study may be considered as fairly representative of the persons admitted to the tuberculosis clinics of the Department of Health in every borough of the city.

Table 2, page 353, shows for each borough the income classification for persons admitted to diagnostic clinics. For the total city, 36.1 per cent reported no income. They were either on home relief or supported by a charitable agency or some other form of assistance. The proportion falling into this class, no income, varied in each borough, from 25 per cent in Queens to 44 per cent in Manhattan. If to this class be added those whose income was less than \$1,000 per year, the result is 69 per cent for the total city who had either no income (except charitable or relief assistance) or had less than \$1,000 per year. By borough, the proportions in this class vary from 55 per cent for Queens to 71 for Brooklyn and 83 per cent for Manhattan. It can be readily seen that a relatively small proportion of persons coming to the diagnostic clinics reported an income of over \$1,000 per year. The proportion which reported an annual income of \$2,000 or more varied from 1.6 per cent in Manhattan to 6 per cent in the Bronx and 6.7 in Queens.

The data shown above indicated that the persons admitted to the diagnostic clinics came mainly from families of low economic status judged by normal income. Income taken in relation to size of family is even more enlightening. Table 3, page 353, shows the average size of family and the number of persons per wage-earner for each income class, also the average size of families with no wage-earners. For families where there were wage-earners, the average size of family increased steadily with income, from 3.1 persons per family for those in the income class of under \$500 per year to 5.3 persons per family for those where income was \$2,000 or more per year. For all income groups except the lowest the average size of family was well above the median size of family, 3.36 for New York City as a whole. The persons per wage-earner

TABLE 2 PERSONS ATTENDING DIAGNOSTIC CLINICS CLASSIFIED ACCORDING TO AMOUNT OF FAMILY INCOME FOR EACH BOROUGH OF NEW YORK CITY

| BOROUGH | TOTAL FAMILIES | INCOME BASED ON WAGE EARNERS | | | | \$2 000 and Over |

varied from 2.4 in families with an annual income of \$2,000 or more to 3.6 persons in those where annual income was from \$500 to \$999. The conclusion may be drawn that these families on the whole are relatively large families and that the earnings of the working members must be spread to include support for a number of persons.

Pneumothorax Service—During the period of this study the Department of Health did not operate pneumothorax clinics in the five boroughs of the city.

The Department of Hospitals rendered this service for the Boroughs of Brooklyn and Richmond. Therefore, Table 4, page 354, shows for the remaining three boroughs the income classification for patients admitted to pneumothorax clinics. The individuals reporting no wage-earners in family comprised 32.9 per cent of the sample studied. Borough classification of this group showed the following variations from 30 per cent in Manhattan to 31 in Queens and 39 per cent in the Bronx. For the total city 57 per cent

* Excluding Central and Vanderbilt Clinics. The Central Pneumothorax Clinic was established later in 1936 and sufficient material was not available at the time of this study. For Vanderbilt Clinic see footnote Table 1.

reported no income, or an income under \$1,000 per year. Borough distribution of this group ranges 52 per cent for Queens, 55 for the Bronx, and 64 per cent for Manhattan. The total family income for persons attending the pneumothorax clinics is considerably higher than for those persons in attendance at the diagnostic clinics especially in the \$2,000 or more income group.

However, in this sample too, it is necessary to relate income with size of family. Table 5, below, shows the average size of family and number of persons per wage-earner for each income class, also the average size of families with no wage-earners.

Discussion

The New York County Medical Society has for several years given consideration to eligibility of patients for dispensary care on the basis of income. Various recommendations have been made, the most recent was in 1936 when the preceding schedule was revised downward 10 per cent and was adopted as follows:

| NUMBER OF INDIVIDUALS | ANNUAL INCOME |
|-----------------------|---------------|
| Single | \$ 900 00 |
| Family of two | 1,260 00 |
| Family of three | 1,485 00 |
| Family of four | 1,710 00 |
| Family of five | 1,935 00 |

The total family income is to be considered where patients and children are working

\$250 to be added for each additional dependent

"Where the individual has had no medical attention during the year and it is estimated that the cost will be over \$25 00 with a local doctor—in other words where the ailment is not a serious or chronic one, the applicant is referred to a local physician. Where the needs of the patient are in the opinion of a physician indicative of expensive medical investigation, this economic standard may be waived at the option of the institution."

In the recent Hospital Survey of New York,⁴ under Out-Patient Service, Mac Curdy recommended the adoption of the above schedule, he stated further "There is common consent among all who meet the problems of the outpatient applicant that stress should be laid primarily upon medical needs and their urgency and that the economic determination should be secondary."

In consideration of the aforementioned economic standards for admission of patients to clinic care it becomes immediately apparent that tuberculosis is a problem somewhat apart from general medical service. It is a communicable disease characterized by its chronicity and debilitating effects. It usually strikes hardest among the adult population and therefore the wage-earning classes. The problem of tuberculosis in the family is much greater than the individual afflicted because the problem of contact supervision is a continuous one over a long period of time. Thus the need of x rays is multiplied by the number of contacts. The problem in families where pneumothorax care is needed is even greater because refills are needed on an average of once every two weeks. The fluoroscope must be available at the time of each refill and the x rays are more numerous than in the average diagnostic clinic case.

Thus while the total family income for persons attending our pneumothorax clinics is higher than in the diagnostic clinics, it is not sufficiently greater compared to the extra cost of treatment to

indicate any abuse of the service. Furthermore it will be noted that the size of the family in pneumothorax cases is proportionately higher than in diagnostic cases.

It is the general feeling among workers in our clinics that the economic level of patients has always been comparable to the present. Patients able to pay for private care as a rule do not seek admissions to our clinics. It is a policy in our work to examine all persons coming to the clinic the first time. If they are found to be able to pay for private care they are urged to make such arrangements but noncompliance will not debar them. We also find that occasionally when patients attending our clinics have increased their income to a point that will permit private care they leave the clinic, and conversely when the economic pressure becomes greater they are likely to return. In many instances this change from the clinic to the practitioner does not work to the best interest of the patient, as the supervision including periodic x rays are not likely to be as frequent when the patient must pay standard fees.

The Chest Consultation Services operated by the Department of Health have, we believe, been a factor in keeping a certain number of cases away from the regular clinics. We make no financial investigation of these cases when referred by the physician. It has been agreed that he will request examination only for those who in his opinion are unable to pay standard consultation fees for chest diagnosis. Any abuse of this service by the practitioner will in the end be reflected in his own practice as well as that of his colleagues. While the prime function of these stations is diagnostic, we do on occasion re-examine and make recommendations for ambulant patients supervised by the practitioner.

Conclusions

The income status of 5,963 individuals representing family units admitted to the tuberculosis clinics of the New York City Department of Health in 1936 has been analyzed.

In the diagnostic clinics 36 1 per cent reported no income and 69 per cent either had no income or less than \$1,000 per year. A relatively small proportion reported income of \$2,000 or more per annum.

In the pneumothorax clinic both the income and the size of the family were higher than the same units in the diagnostic clinics.

Considering the chronic nature of tuberculosis, the need for long-term supervision, and repeated x-rays for the case, as well as contacts, it is not believed that our clinics are being used by those able to pay standard fees.

The Consultation Service for practitioners operated by the Department helps to keep a large number of cases under private care. They are not clinic

cases and yet they are unable to pay for consultation service at existing fees in private practice. This clinic provides the specialistic service needed without cost. The patient can afford ordinary medical fees and, therefore has a complete service under the private doctor.

HEALTH IMPROVING? OF COURSE!

That, in essence, was the comment of Surgeon General Thomas Parran on our steadily rising national health figures, as expressed in his address at the meeting of the American Public Health Association in Kansas City a few weeks ago. He admitted that "in discussing public health in the United States it is tempting to dwell upon past accomplishments. It is pleasant to point with pride to the lowest general mortality on record, to a further decline in the tuberculosis death rate, now less than 50 per 100,000, to a continually lower infant mortality and a significant reduction in the mortality of women during childbirth, which is 15 per cent lower this year than last. Similar satisfaction could be taken in the low level of death rates from typhoid fever, diphtheria, and many other preventable diseases.

"Such rates, however," he added, "are based upon past records and compared with death rates of earlier days. If medical science were static, past records would be a useful yardstick. Medical science, however, is not static. Al-

most every year additions are made to scientific knowledge which make it possible for us to do more than previously was possible in the prevention of disease. Many tools for better health are being forged in our scientific laboratories.

"There is every reason why we should accomplish more now than in the past. Moreover, an awakening public sentiment and the increasing interest of doctors in disease prevention as well as cure, make it possible for us to do far more than has yet been done in putting medical science to work for all of the people. Sickness and death rates of previous years, therefore, are inadequate yardsticks for the present and are useless as goals for the future.

Public health is a dynamic science. The horizon of knowledge is being extended year by year. Our plans for its application should embrace not only the knowledge we now have but should forecast the inevitable accretions to knowledge which year by year will make it possible to prevent deaths now considered inevitable."

"You must be on a war diet."

"Why on a war diet?"

"Because all of your food goes to the front."

The incidence of diphtheria is a direct reflection of the efficiency of the medical profession of any civilized community.—*Pittsburgh Medical Bulletin*

RESTORATION OF MUSCLE BALANCE IN THE TREATMENT OF OBSTETRICAL PARALYSIS

J B L'EPISCOPO, M.D , BROOKLYN

THIS contribution is a report on the progress of the restoration of muscle balance at the shoulder since the first publication on this subject in 1934

Although we would like to discuss obstetrical paralysis thoroughly, we cannot do so because of the limited time allotted to its discussion at this time. Therefore, we will only take up the so-called upper-arm type

In order to properly understand the treatment, a brief description of the pathologic anatomy seen in that type of case, I believe, is essential

First, let us consider the muscles about the shoulder. We have all noticed that there is an early tendency for certain muscles, adductors, and internal rotators of the shoulder to shorten or contract. These are essentially the subscapularis, the pectoralis major, teres major, and the latissimus dorsi. These produce an internal rotation of the humerus, causing the head of the humerus to lie posteriorly in the glenoid cavity and as the humerus grows, a torsion deformity of the entire bone tends to develop. As the humerus is maintained and grows in the internally rotated position, it also causes a change of direction of the muscle fibers of some of the muscles attached to that bone, particularly the deltoid, so that instead of the fibers of this muscle going straight downward and outward, they are directed downward and inward. Consequently, when this muscle contracts, instead of the arm going outward at right angles to the trunk, the muscle tends to bring the arm mostly forward and somewhat outward. This is especially evident in cases where the passive scapulohumeral motion is very good. Nevertheless the active abduction is very poor, because the deltoid fibers, being wrongly directed,

pull the arm forward instead of laterally. Because of the malposition at the shoulder, the glenoid, as well as the head and anatomic neck of the humerus, do not develop properly. The glenoid tends to be shallow. There is a torsion growth of the neck and head of the humerus, so that the head points posteriorly. This position, which is at first simply postural, and is easily corrected in the early stages, later becomes fixed.

We believe that all these changes are secondary to posture, although Scaglietti contends that the majority are due to a separation of the epiphysis during delivery. We are not convinced yet that his theory explains adequately these late changes that are found, particularly if we include deformities of the elbow and forearm, where there is often definite contracture of the biceps and pronator radii teres muscles, and, occasionally, the flexors of the wrist, especially the flexor carpi ulnaris, although the latter very rarely persists after the first or second year. Because of the constant pull of the internal rotators of the shoulder, the external rotators are stretched and further weakened.

It will be seen from this brief description of the pathologic anatomy that the extremity must be maintained in a position of deformity. The arm is held in internal rotation and slight abduction. Most men have hitherto described the arm as being adducted, but if we look carefully at the shoulder, we will see that it really is in slight abduction. We have all made this mistake because we have noticed the limited abduction and therefore have erroneously concluded that the arm must be adducted. The forearm is pronated and the elbow flexed. We feel that the abduction is due to partial poste-

*Read at the Annual Meeting of the Medical Society of the State of New York New York City
May 10 1938*

rior dislocation of the shoulder, in spite of the contracted adductors. We have described the pathologic anatomy only briefly and grossly, we feel that the finer and more complete details are not yet known and that more study and research is necessary. We have never had the opportunity to study a case in the autopsy room. We feel that postmortem studies of this lesion will help us in determining the exact and minute details of the pathology.

Treatment

This may be conveniently considered under two headings: the early or conservative treatment, and the late or surgical treatment. We are of the opinion that early treatment should be conservative, in spite of the reports of a number of authors who advise surgical repair of the brachial plexus within the first few months of life. Our experience has shown us that cases so treated have not been benefited sufficiently to warrant surgical intervention and that those cases that have shown improvement, to our mind, have not shown any better improvement than other cases treated conservatively. On the other hand, we have seen cases that were left with a completely flail, flaccid paralysis of the extremity following early surgical intervention, but we have never seen a case conservatively treated that was left with a completely flail arm.

It is our practice to place the arms of these infants, soon after birth, in abduction and external rotation. In the newborn this can very easily be accomplished by making a tightly fitting cap for the baby and pinning the sleeve of the shirt to this cap, on the side of the head. After a few months a molded plaster-of-Paris splint is applied in this position. Both these methods make it easy to move the child about, particularly in nursing, without disturbing the position of the arm. If contractures tend to occur after the first few months, daily manipulations are advised to stretch the contracting muscles. The mother can usually be easily

taught how to do this. We want to give a word of warning in the application of the abduction splint. The arm should be placed in about 70° of abduction from the trunk. Elevation of the shoulder should be avoided as we have seen subglenoid dislocations occur when the arm has been elevated for too long a period. This conservative treatment should be followed for a relatively long period, five or six years. Many children will have good, useful arms by that time with little or no deformity. However, if deformities should persist or tend to increase, then surgery is indicated.

If we admit that the deformities are due to a loss of muscle balance between antagonistic muscles, which we think is the case, our first concern should be to re-establish this muscle balance to approach the normal as much as possible. As mentioned above, the most imbalance is between the internal and external rotators of the shoulder, the internal rotators being contracted and apparently more powerful than the external rotators. This can be overcome by releasing the tight internal rotators, that is, the subscapularis, pectoralis major, the latissimus dorsi, and teres major, as advocated by Sever. This is a very satisfactory operation but in many cases it has only a temporary effect, as the deformity tends to recur. The same may be said for the osteotomy of the humerus as practiced mostly in Europe. These operations, of course, simply correct the deformity but make no attempt to restore muscle balance. By that we mean that no attempt is made to strengthen the weaker external rotators and to weaken the strong internal rotators.

For the past seven years we have been transplanting the teres major and latissimus dorsi muscles from the medial aspect of the humerus to the lateral aspect, thus changing the action of these muscles from internal rotators to external rotators, thus weakening the internal rotators as a group and strengthening the external rotators as a group. The reason we picked out these two muscles is that they lend themselves to transplantation more

Figure 1 A Shows the anterior incision. B Shows the exposure of the deeper structures and the capsule of the shoulder with the pectoralis major tendon cut near its insertion. C Shows the latissimus dorsi tendon completely exposed and the subscapularis tendon re-

leased by cutting the capsule of the joint. D Shows the latissimus dorsi and teres major tendons being sutured before cutting. E Shows the latter two tendons cut and being held by sutures before they are transposed posteriorly.

easily than some of the other internal rotators.

Before doing any muscle transplantation, however, we must bear in mind

that no transplanted muscle will work efficiently in the presence of deformity which would mechanically interfere with its function at its new insertion. There

fore, we must correct any existing deformity by releasing the internal rotators, but instead of cutting the subscapularis according to the method of Sever, we cut the capsule of the joint according to the method of Fairbank, as this releases not only the subscapularis but also the contractures of the capsule. The pectoralis major is also cut. In the very late cases where there is torsion of the upper end of the humerus and the fibers of the deltoid are directed downward and medially, a circular osteotomy is done at the upper end of the humerus. This must be done above the insertion of the deltoid muscle so that as the lower fragment of the humerus is rotated outward, the fibers of the deltoid muscle are directed straight downward. The combination of these procedures not only corrects the deformities and restores muscle balance, but this muscle balance is maintained by the transplantation of the two internal rotator muscles.

The lower arm often requires correction of the flexion of the elbow and pronation of the forearm. The flexion of the elbow is not sufficiently troublesome, as a rule, to interfere very much with function, but the pronation is at times quite disabling. This we have corrected by doing a subperiosteal resection of the pronator quadratus muscle from the ulnar side of the wrist and a transplantation of the pronator radii teres muscle. As we all know, this muscle starts at the medial condyle of the humerus, and then goes downward and outward and wraps itself around the middle of the radius from without inward. The insertion of this muscle is completely stripped, taking some periosteum at the same time so that the tendon will be sufficiently long. Then the lower end of the muscle is wrapped around the radius, from within out and inserted at its original insertion on the back of the radius. In other words, the tendon is pulled out and then passed between the radius and ulna, after making an opening through the interosseous membrane close to the radius, so that the muscle insertion now wraps around the radius in the opposite direction to its

normal one, thus acting as a supinator instead of a pronator of the forearm.

Technique of Operation

The operation as described originally has been somewhat modified and, we believe, simplified. Only the modifications will be described here.

We are using the same anterior and posterior skin incisions. The tendons of the latissimus dorsi and teres major muscles are now cut through the anterior incision, as close to their insertion as possible. They are ligatured, passed posteriorly by means of the ligature and sutured under a thin osteoperiosteal flap, just above or at the origin of the outer head of the triceps muscle, as in the original operation, except that no heavy bone flap with drill holes is made. The transplanted tendons seem to hold just as well as they did under the heavy bone flap.

Since 1931, we have performed this operation on 16 patients. Fifteen of these had obstetrical paralysis and 1 had a spastic hemiplegia. The latter case was done because he maintained the arm in extreme internal rotation, although this could be overcome passively. We felt that weakening the internal rotators and strengthening the external rotators might improve function. The result was not very satisfactory to us as far as functional improvement was concerned, but there was some cosmetic improvement in that the arm was not maintained in extreme internal rotation. The 15 cases of obstetrical paralysis have all been definitely improved functionally.

Discussion

Dr Leo Mayer, *New York City*—Dr L'Episcopo has presented a thoughtful paper which can be divided into three parts. The first deals with the pathological changes in birth paralysis. These are of the utmost importance since the more accurate our knowledge of pathology the more exact can be the indications for treatment.

The second part deals with the conservative

Figure 2 A Shows the posterior skin incision parallel to the posterior fibers of the deltoid muscle. B The deltoid and long head of the triceps muscles are shown exposed and the relaxed teres major muscle visible. The teres major and latissimus dorsi tendons pulled out of the posterior incision by means of ligatures.

D Teres major and latissimus dorsi being passed under the long head of the triceps and the deltoid retracted out of the way. The osteoperiosteal incision at the attachment of the lateral head of the triceps is shown before the transplanted muscles are sutured in place. E The transplanted muscles are shown sutured under the periosteal flap.

method of treatment. He calls attention to the abduction contracture which may develop as a result of the use of an abduction brace. My experience shows that this contracture may develop very early and that it is only by the early use of massage and manipulation that it can be avoided. Important though it is to overcome the internal rotation contracture, this should not be done at the expense of developing an equally undesirable abduction contracture. In many patients who are referred to me, an abduction splint has been left on for many months at a time. In these patients it is particularly difficult to overcome the abduction contracture and in some cases operative procedures have been necessary before a normal alignment between the shoulder and scapula can be established.

The third portion of the paper deals with the operative correction. Dr L'Episcopo has made an important contribution to this field. Although the release of the internal rotators has helped many patients, their transference to the posterior aspect of the humerus adds considerably to the strength of the external rotators. In the cases in which I have used this method, the results have been gratifying. To overcome pronation contracture I find the following procedure more effective than the Tubby operation which Dr L'Episcopo has mentioned. The tendons of the flexor carpi radialis and pronator radii teres are cut away from their insertion, freed as far upward as possible, fastened to one another by a few silk sutures and then brought over the ulnar side of the forearm in a spiral line downward and backward to the posterior surface of the radius just above the wrist. Here they are fastened to the bone through a drill-hole passing from behind forward.

May I also call attention to the excellent correction of severe internal rotation contracture by the stripping operation of Dr Klemberg.

Dr J E Milgram, Brooklyn—Dr L'Episcopo's contribution to the surgery of the obstetrical internal rotation contracture at the shoulder is of major significance. Its very simplicity of plan and execution (transformation of deforming internal rotators into badly needed external rotators) was enough to earmark his first publication for all of us. I will, if I may, confine my discussion to the shoulder and the elbow of Erb's Palsy. I was much gratified to hear Dr L'Episcopo's remark that while most men have hitherto described the arm as being adducted—"it is really in slight abduction."

The abduction contracture of the shoulder is frequent (16 of 23 cases), real, severe, persistent, disabling, deforming, and what is most impor-

tant, as a rule unnecessary. There is an increasing number of cases in which the conservative treatment is overdone and an additional deformity has resulted. It is usually associated with a contracture of the backward extensors of the shoulder. The arm, at rest, hangs away from the side and even passively cannot be brought to the side without making the scapula poke out awkwardly. If the arm is brought forward in the horizontal plane, the scapula is dragged with it in unison so it comes to lie almost on top of the shoulder, again in awkward fashion.

In 1932, I stressed the recognition and causation of the abduction contracture and urged an operative plan which has since been performed on several patients at the Hospital for Joint Diseases, with moderate success. It consists essentially of elongation of the deltoid and the superior shoulder joint capsule. The first patient I operated lost some abduction as a consequence of overcorrection. The next two patients whom Dr Leo Mayer operated were less radically corrected and the end results were better. I had hoped that Dr Mayer would find time to relate attempts by operative methods to correct the abduction contracture. They are essential but have not been an unalloyed joy. The deformity is preventable and I would here stress prevention.

May I call your attention to the fact that the abduction contracture is really an orthopedic deformity resulting from overtreatment. In time the original abduction external rotation deformity changes to an abduction internal rotation deformity, as the brace is left off and the active internal rotators come into play. The shortened deltoid and upper shoulder capsule, however, maintain the abductor component.

We were all taught to keep the arm in the flagman's position until the nerves grow back, months and years, if necessary. In a newborn child with a traumatized shoulder, even three weeks of this position will result in a contracture easily recognizable, and difficult to undo.

I have, therefore, employed the following schedule:

- 1 The arm is supported, instead, in the military-salute position from birth, using a light wire padded splint (in 90° abduction, 45° forward flexion, 90° external rotation of the forearm).

- 2 After two weeks, the arm is left free for several short periods, to fall to the side.

- 3 As return occurs, the splint is more frequently left off during the day although the child sleeps with it at night.

4. Passively the shoulder is regularly brought through all ranges of passive motion after the third week. If the nurse or physiotherapist can recognize the abduction contracture, it will not be added to those unpreventable deformities for which Dr L'Episcopo's operation is of such value.

A word as to the elbow

1. Long routine brace fixation of the infant's elbow in flexion must be employed only with understanding and periodic stretching into extension. Otherwise permanent loss of terminal extension will develop regularly and persist almost indefinitely.

2. Limitation of elbow extension later occurs when the arm hangs in abduction and internal rotation. Gravity flexes the elbow and bone growth fixes and limits the ranges of terminal extension in time.

If active flexion is absent at the elbow and the biceps is gone, the Steindler flexor shift upward of the forearm flexors has proved of immediate value.

In a few cases a peculiar asynergia of the elbow flexor and extensor appears. In three such cases under my care, each patient has shown a weak biceps and a stronger triceps. When he tries to bring his hand to his mouth it becomes rigid at a variable degree of flexion.

the triceps contracting synchronously with the biceps and freezing the latter's effect so that the patient is unable to bring his hand to his mouth.

In one case after a preliminary test of anaesthetizing the triceps by novocaine, I performed a triceps tenotomy. Since then the patient has been able to voluntarily bring his hand to his mouth with ease.

Such disturbances of reciprocal innervation of opposing groups of muscles in Erb's Palsy probably exists frequently about the shoulder and makes one wonder whether avulsion of the roots from the spinal cord has not interfered with upper motor neurone control at local levels in the cord. I am not aware of cord studies which might settle this point.

As Dr L'Episcopo reminds us we have yet much to learn about the true pathology of apparently simple Erb's Palsy.

Lantern slides are presented of (1) an abduction contracture in a three weeks old infant (2) a persistent abduction contracture in a three year-old child (3) an abduction contracture in a three-month-old infant and the corrected contracture at the age of three years the result of almost two and one half years of continuous stretching indicating that prevention would have been easier than cure.

BIG NICK IN GRIM REAPERS SICKLE

The first full year of organized battle against pneumonia in New York City under the auspices of the Health Department's pneumonia control bureau was concluded on December 31.

Exact figures on the bureau's accomplishments will not be available for some time, but estimates show that the use of serum to fight the 60 per cent of pneumonia cases for which serum can be used, has been doubled.

A rough estimate on the number of lives saved would indicate that somewhere between 700 and 1,000 persons with pneumonia who would have died in 1938 are now alive, thanks to serum and its increased use under the pneumonia bureau.

LOOPHOLE BADLY IN NEED OF A STOPPER

By a strange anomaly a layman cannot prescribe for one patient but he can prescribe for a million. A leading New York City doctor held in his hand the other day the circular of a medical preparation put out by a manufacturer who made no claim to be a physician. The preparation had in it liver extract, ascorbic acid, vitamin B, copper citrate, oil of peppermint, ferrous sulfate and cottonseed oil. No chemist would fill that prescription if it were written by a layman, said the doctor but a layman can put it up and prescribe it for thousands and millions of people he never saw! There is a legal loophole badly in need of a stopper.

"What did the doctor do for your absent mindedness?"

"He prescribed some pills."

"Did they help?"

"I forgot to take them."—*Rocky Mt Med J*

SULFANILAMIDE IN THE TREATMENT OF CHANCROID

BORRIS A. KORNBLITH, M D , ADOLPH JACOBY, M D , and
MICHAEL WISHENGRAD, M D , New York City

(From the Central Clinic, Bureau of Social Hygiene, Department of Health, City of New York)

THE causative agent in chancroid is the Ducrey organism, a gram negative streptobacillus of moderate virulence. The very good results obtained by the use of sulfanilamide in the treatment of streptococcus infections suggested its trial in chancroid infections.*

The results of the use of sulfanilamide in a series of 10 cases at the Central Clinic have been so consistently gratifying that they warrant this preliminary report. Among the 10 cases here reported, there were 9 men and 1 woman. The lesions ranged from one ulceration on the shaft of the penis to six ulcerations on the prepuce and a complete sloughing of the glans penis. The duration of the lesions varied from three weeks to fifteen months.

The criteria used for diagnosis were

- 1 A reasonably adequate lesion
- 2 A positive smear for Ducrey organisms
- 3 A positive Ducrey skin reaction
- 4 A negative dark field examination
- 5 A negative Wassermann reaction
- 6 A negative Frei test

Seven of the cases reported conformed to the above criteria. In 3 patients, in whom syphilis was also present, the luetic etiology of the local lesion was ruled out—one was a congenital luetic and the other two had been under antiluetic treatment for about one year, prior to the onset of the present disease. The last patient (Case No. 10) appeared at the clinic with an acute lesion and a three plus Wassermann on three different occasions. The dark field examination, however, was negative and the Ducrey smear was repeatedly positive.

Therapy also helps to differentiate chancroid from a luetic lesion. A primary luetic lesion does not respond to sulfanilamide and takes its natural course. This has been shown in experimental work done on rabbits,¹ and in our own experience, in one patient. This patient, a twenty-two-year-old negro, appeared with a flat 2 cm ulceration at the coronal sulcus. The Wassermann test, smear for Ducrey bacillus, and dark field examination were negative. Inasmuch as the lesion appeared clinically like a chancroid, sulfanilamide was given for five days. Despite this treatment the lesion, which had been present for six weeks, spread, became indurated, and was then diagnosed as a primary chancre due to syphilis. A dark field examination at this time showed numerous spirochete pallida. While sulfanilamide has no effect on luetic lesions, antiluetic therapy has no beneficial effect upon concomitant chancroidal lesions developing during the course of anti-syphilitic treatment. Thus, antiluetic medications and sulfanilamide may be given simultaneously. The last patient (Case No. 10) responded favorably to sulfanilamide.

An inguinal adenitis which was discrete and nonsuppurative was present in 6 of the 10 cases reported.

A smear for Ducrey bacilli was positive in all cases. Whereas it was possible to demonstrate the organisms consistently before treatment was begun, the organisms were not demonstrable after forty-eight hours of treatment with sulfanilamide. The Una Pappenheim stain, methylene green pyronine, was found most satisfactory. The organisms stand out as red streptobacilli arranged in streaks and parallel rows.

The material for skin testing² was obtained from Case No. 1, from a bubonulcus.

* We are indebted to Dr. Gregory Schwartzman of the Mount Sinai Hospital for this suggestion which we followed through.

on the shaft of the penis. It was prepared in the same way as Frei antigen. This material gave positive results in chancroid cases and negative tests in cases of lymphogranuloma venereum or lues

Method of Treatment and Results

For the first five days, the patient was given 80 grains of the drug per day—20 grains after each meal and before bed time. From the sixth to the fifteenth day, inclusive, 40 grains per day were administered—10 grains after each meal and 10 grains before bedtime. After this period, treatment was stopped whether or not the lesion was healed. The entire treatment was ambulatory.

No untoward effects were noted in this group of cases. The patients were cautioned to stop the drug if a diarrhea developed, and in case of constipation not to use a saline cathartic. They were likewise instructed not to drink more than one quart of fluid during a twenty four-hour period. The only other treatment advised was the use of soap and water to cleanse the local lesion twice daily.

The average duration for treatment was fifteen days and an average amount of 600 grains of sulfanilamide was given. The average time for healing was about two weeks. The fact that there were no complications due to treatment, also the fact that all of the cases responded favorably, seems somewhat unusual. There will probably be cases with complications and resistance to treatment but up to the present we have not encountered them.

It is hoped that in the near future a larger group will be available for study and give us a broader base for more accurate evaluation of this therapy.

A table and brief description of these 10 cases follows.

Case Reports

Case 1—J.M. 26 white, male, complained of small ulcerations on the shaft of his penis accompanied by enlarged inguinal glands in both groins, of five weeks duration. The ulcerations progressed and the glands became painful. Four weeks after the onset, he developed a soft

• Case 7 Under antiseptic treatment for fourteen months before sulfanilamide treatment was begun.
+ Case 8 Under antiseptic treatment for nine months before present lesion appeared.
+ Case 9 Case of congenital lues. Developed present lesion while under antiluetic therapy.
+ Case 10 Asymptomatic lues. Dark field negative—at time of admission.

Old case of lymphogranuloma venereum.

boggy swelling about the size of a hazel nut on the dorsum of the shaft of the penis. In addition, he developed three separate large ulcerations around the corona.

Examination A ragged ulceration was present under the prepuce, this measured 4 X 2 cm. There was a bilateral slightly tender inguinal adenopathy. The nodes were discrete, and there was no evidence of breaking down. A 2 cm bubonulus was present on the dorsum of the shaft of the penis. This was fluctuant. After three days observation this bubonulus was aspirated and 5 cc of pus obtained. The skin over the bubonulus broke down and left a ragged ulceration about 2 cm in diameter.

Laboratory Findings The Wassermann was negative, the Frei test was negative, smears from the ulceration for Ducrey bacilli were positive. The pus aspirated from the bubonulus was treated at 60 C for two hours on two successive days, (fractional inactivation, similar to the preparation of Frei material). This material was used for the skin testing. It proved to be a potent antigen, giving positive reactions in proved cases of chancroid disease and negative intradermal reactions in control cases (Luetics and lymphogranuloma cases). Dark field examinations were repeatedly negative.

Treatment For five days the patient was given two doses of 5 cc of 1 per cent potassium antimony tartrate. His lesion progressed unabated. At this point sulfanilamide was given, 80 grains for a period of four days and 40 grains for an additional period of nine days. The only other treatment given consisted in cleansing the local lesion with soap and water. The total duration of treatment with sulfanilamide was thirteen days, the total amount of sulfanilamide used was 680 grains or 40.8 grams. The patient made a rapid recovery, signs of recession were evident as early as forty-eight hours after sulfanilamide treatment was begun. All ulcerations healed completely. The swelling of the inguinal nodes receded.

Follow-Up The patient was seen again in January, 1938, three months after the onset. There was no evidence of any recurrence.

Comment The history and progress of this case are particularly noteworthy. The lesion including a bilateral adenopathy and the formation of a bubonulus on the shaft resembled lymphogranuloma more than anything else. The further course, however, established a correct diagnosis.

Case 2—G F, 24, Puerto Rican male, complained of ulcerations on the shaft of his penis of two months' duration.

Examination The patient had two separate

ulcerations on the dorsum of the shaft of his penis near the corona. These measured 2 cm and 1½ cm in diameter, respectively. He likewise had a bilateral moderate discrete inguinal adenopathy.

Laboratory Findings The Wassermann test was negative, the Frei test was negative, the Ducrey skin test was positive. Smears for Ducrey bacilli were positive. A dark field examination was negative.

Treatment The patient was given a total of 660 grains, or 57.6 grams of sulfanilamide in nineteen days. His ulcers had healed completely at the end of two weeks.

Follow-Up The patient was seen again at the end of one month, entirely well. There was no evidence of recurrence.

Case 3—H S, 27, negro male, had an ulceration on the corona of one month's duration.

Examination The patient had a single discrete ulceration on the right side of the corona measuring 1 cm in diameter. There was no evidence of inguinal adenopathy.

Laboratory Findings The Wassermann was negative, the Frei test was negative, the Ducrey skin reaction was positive. A dark field examination was negative.

Treatment The patient was given a total of 440 grains or 26.4 grams of sulfanilamide in ten days. At the end of ten days the lesion had healed completely.

Case 4—R W, 36, male negro, complained of ulcerations on his penis of three weeks' duration.

Examination A single flat 8 mm ulceration was present on the dorsum of the shaft of the penis. A left inguinal adenopathy was present.

Laboratory Findings The Wassermann was negative on two occasions in the interval of one month. The Frei test was negative, the dark field examination was negative, the Ducrey skin reaction was positive, and smear for Ducrey bacilli was positive.

Treatment The patient was given a total of 720 grains or 43.2 grams of sulfanilamide in fourteen days. At the end of two weeks the lesion had entirely healed.

For two weeks before the patient appeared at this clinic, he had received iodoform in ether for local application to his lesion. This produced no good effect.

Follow-Up The patient was seen two weeks later, no evidence of recurrence.

Case 5—J B, 22, colored male, complained of many small ulcerations on his penis.

Examination Six distinct ulcerations were found on the penis, three on the prepuce, each measuring 8 mm in diameter, 2 ulcerations were present on the glans penis near the urethra, these

measured 6 mm one large oval shaped undermined ulceration was present on the penis on the dorsal surface of the glans at the coronal sulcus. The inguinal glands were shotty in both groins.

Laboratory Findings The Wassermann was negative, the dark field examination was negative, the Ducrey smears were positive, the Ducrey skin test was positive. The Frei test was negative.

Treatment The patient was given a total of 1,020 grains or 60.2 grams of sulfanilamide in nineteen days. At the end of two weeks, however the lesions had completely healed.

Case 6—J.M. 27 negro male had a sore on his penis of four weeks' duration.

Examination Two ulcerations were found on the prepuce 2 cm and 1 cm in diameter respectively.

Laboratory Findings The Wassermann was negative, dark field examination was negative, smears for Ducrey bacilli were positive. Ducrey skin test was positive. The Frei test was negative.

Treatment The patient was given a total of 640 grains or 38.4 grams of sulfanilamide in fourteen days. At the end of this period both ulcerations had completely healed.

Follow Up The patient was seen three weeks later no evidence of recurrence.

Case 7—S.E. 39 negro male was admitted for antiluetic treatment on July 8 1936. At that time his Wassermann reaction was 4 plus. On June 1, 1936 he noticed a small pustule at the urethral opening. In spite of antiluetic treatment, this lesion enlarged and covered at least one third of the glans penis. In July one month after the onset he developed a marked paraphimosis.

Examination After three months' observation the urethra beginning at the meatus and extending 1 cm proximally was entirely eroded the glans penis itself was practically entirely sloughed. A deep ragged ulceration replaced the tip of his penis. This was surrounded by a hard indurated edge and surmounted by a very tense paraphimosis. The lesion resembled a carcinoma of the glans penis.

Laboratory Findings The Wassermann in July 1936 was 4 plus. A smear for Ducrey bacilli was positive the Frei test was positive. A dark field examination was negative.

Treatment The patient was given intensive antiluetic therapy between July 1936 and September 1937. This had no effect upon his local lesion. In view of his positive Frei reaction in intravenous injections of Frei antigen were given for a period of eight months. This produced no improvement. A course of tartar emetic was

given likewise six injections of fuadm produced no improvement. In September 1937 fourteen months after his original admission the local lesion had receded somewhat but refused to heal in spite of all the treatments given above. Smears for Ducrey organisms were persistently positive. At this point it was decided to use sulfanilamide. The patient was given 80 grains a day for five days and 40 grains a day for ten succeeding days. The patient took a total of 800 grains in fifteen days. In the course of thirty nine days after the beginning of this treatment the patient's lesion healed completely. His glans penis although much smaller and deformed showed a pale white epithelium which was firm and clean and showed no tendency to breaking down.

Follow Up The patient was followed for three months after healing took place, there was no evidence of recurrence.

Case 8—E.G. 26, colored male had ulcerations on the frenum of three months' duration.

Examination The patient showed two ulcerations each 2 cm in diameter one on the dorsum of the penis and the other at the frenum.

Laboratory Findings The Wassermann was 4 plus the patient had been under antiluetic treatment since January 1936. The Frei test was negative the smears for Ducrey bacilli were positive. A dark field examination was negative.

Treatment The patient was given a total of 800 grains or 48 grams of sulfanilamide in thirty four days. The ulceration healed completely at the end of three weeks.

Follow up The patient was seen one month after treatment without evidence of recurrence.

Case 9—H.J. 31 male negro who was under treatment for congenital syphilis complained of ulceration on his genitalia and large inguinal glands of one month's duration.

Examination Three small flat 5 mm ulcerations were present on the prepuce in addition to a right inguinal adenopathy.

Laboratory Findings The Wassermann reaction was 4 plus a dark field examination was negative the smears for Ducrey bacilli positive the Ducrey skin test was positive the Frei test was negative.

Treatment The patient was given a total of 560 grains or 33.6 grams of sulfanilamide in nine days. At the end of this time all the lesions were healed completely and the inguinal adenopathy had receded.

Follow Up The patient was seen two weeks later no evidence of recurrence.

Case 10—A.B. 37 negroes complained of a painful ulceration on her genitalia of three weeks' duration.

Examination A punched out irregular 3 cm ulceration was present on the right labium minus at a distance of 1 cm from the external urethral meatus. Shotty inguinal nodes were present in the right groin.

Laboratory Findings The Wassermann reaction was 3 plus, a dark field examination was negative repeatedly, smears for Ducrey bacilli were positive, the Ducrey skin reaction was positive, the Frei test was negative.

Treatment The patient was given a total of 640 grains, or 38.4 grams of sulfanilamide in thirteen days. At the end of eleven days the lesion had completely healed.

Follow-Up The patient was seen two months later, there was no evidence of recurrence. Antiluetic therapy was begun after sulfanilamide was given.

Summary and Conclusions

1 Ten cases of chancroid infections treated by sulfanilamide are presented.

2 All of these cases responded favorably to this method of treatment.

3 All cases healed after an average of fifteen days' treatment with the administration of 800 grains of sulfanilamide in divided doses.

4 Sulfanilamide therapy may possibly

be used as a means of differential diagnosis of genital lesions.

5 Since this series is small, further study is necessary with larger groups of cases to determine the presence of resistant cases and for confirmation of our present findings.

Addendum

Since this report was submitted for publication, 65 proved cases of chancroid have been followed. The results have been uniformly excellent. There has been no failure or recurrence. All of the cases were healed after two weeks of treatment with sulfanilamide alone.

The first 24 cases were discussed (case presentation) before the Section of Dermatology and Syphilis at the New York Academy of Medicine in March, 1937. At that time the literature contained no previous reports of similar findings.³

A CASE OF A COMMON DUCT STONE IN AN EARLY TYPHOID CARRIER

HARRY DAN VICKERS, M D , Little Falls, New York

THERE have been reported many cholecystectomies performed for the cure of the typhoid carrier state. The procedure is recognized and accepted not only in the treatment of the carrier state, but also as a public health practice in the prevention of the spread of typhoid fever. The gallbladder presents the typhoid bacilli with an excellent culture medium under conditions of poor drainage and stagnation from which the bacilli are fed continually into the intestinal tract. Poor drainage and stagnation result when the gallbladder becomes inflamed, as it does in a considerable percentage of typhoid fever cases. Furthermore, the presence of stones, porous in nature, offers a perfect haven for the bacilli, and further interferes with drainage. Thus, cholecystectomy removes a stagnant pool of culture media from which typhoid bacilli are fed into the intestinal tract.

The following is the report of a case whose gallbladder had been removed prior to an attack of typhoid fever, but who nevertheless became a typhoid carrier. This was most puzzling until she came down with the classical signs and symptoms of a common duct stone. It was reasoned that there was an obstruction of the biliary tree by one or more calculi which was reproducing the stagnant conditions of the carrier gallbladder in the bile ducts, and had made easy the development of the carrier state. In this instance there was no focus on infection to remove, but it was assumed that if free drainage of the obstructed ducts could be effected the bacilli would soon be washed out of the biliary tree and a cure would result.

The patient, M S, age 49, entered the Little Falls Hospital December 23, 1935, with a fever of undetermined origin. The history was that she had gradually developed fever a week previous. She

had chills, sweats, anorexia, headache, constipation, and frequent epistaxis, a combination of symptoms very suggestive of typhoid. She became weaker and was hospitalized by her local physician. Her past history was of interest in that she had had a cholecystectomy in 1925. At that time she had had right upper quadrant pain which radiated to the shoulder, indigestion, aversion to fats, belching, and constipation. She had not been jaundiced. Postoperatively, however, she was jaundiced for six days, but made a complete recovery. She remained in good health until 1933 when she had an attack similar to the above, except that she had chills fever, and sweats, and had to have hypodermics for the pain. She has had several milder attacks since.

Physical examination on admission was negative for any remarkable findings. The patient was of the short plump type. There was no rash, or palpable spleen. There was a healed right upper rectus scar, but there was no tenderness in its vicinity. A diagnosis of typhoid fever was made by agglutination tests and isolation of the typhoid bacillus by blood cultures. Treatment was symptomatic and supportive. The disease as measured by the fever continued for about three weeks. The temperature continued at about 100 F for another week, then spiked between 99 F and 103 F for a week. For the next four weeks she ran a low grade fever, but her general health was good. During this time the stools were positive for typhoid organisms.

On February 20, the patient became acutely ill with what appeared to be a common duct obstruction. She had right upper quadrant pain of a stabbing nature which radiated to the back, chills a temperature of 103 F, and sweats. There developed a deepening icterus

The attack subsided in a week, though there remained a varying amount of residual pain. At this time her urinalysis was normal, rbc 4,300,000, wbc 7,000, hemoglobin 63 per cent, differential, polys 62 per cent, monocytes 37 per cent, basophiles 1 per cent. Icteric index 35. Van den Bergh—delayed direct over four minutes, indirect 3 mgm per 100 cc. A flat abdominal plate was negative for calculi. Duodenal drainages were done on two successive days and the specimens cultured for typhoid bacilli. Both were positive. A gastric specimen was negative. Stool cultures were still positive.

The presence of typhoid bacilli in the upper intestinal tract as indicated by the positive duodenal drainage specimens seemed to indicate that the bacilli were being harbored in the biliary tree. Since it was established that the patient had a common duct stone which was interfering with the free drainage of bile from the hepatic ducts, it was assumed that this condition was the cause of the patient being an early typhoid carrier. Thus would be an especially strong assumption if the bacilli disappeared after surgical drainage of the biliary tract.

At operation on March 8, a 3.5 cm gallbladder stump was found to remain. Two small stones were embedded in its fibrous wall. A considerably dilated thickened common duct was explored, and a round calculus, 1 cm in diameter, was removed from the region of the ampulla of Vater. A No. 18 F catheter was sutured in the distal portion of the duct and the abdomen closed. Recovery was uneventful, the tube being removed on the eighth postoperative day. Cultures of the gallbladder wall were positive for B

typhosus, as were a cystic duct node, a specimen of common duct bile, and the unsterilized common duct stone. The sterilized stones from the gallbladder stump were negative.

Cultures were taken almost every day of the bile escaping from the tube, and later from the sinus until it healed, April 3. Stool cultures were taken at intervals, and finally of bile obtained by duodenal drainage. The cultures of the bile from the wound were constantly positive, there being 18 in all. There were 11 positive stool cultures before the first negative on April 10, thirty-three days after the operation. There were then four negative stool cultures, but on April 27 there was one positive. Following this positive culture the stools were consistently negative, there being fifteen in number. Four duodenal drainage cultures in the early part of May were negative. Cultures of the urine were also negative. On her discharge from the hospital May 16, the patient had almost regained her former weight, and had no symptoms referable to her digestive or biliary systems. She was considered cured of being a typhoid carrier.

About one month later the patient developed a painful subcutaneous swelling beneath her left breast. She was admitted to the hospital, and the abscess opened and drained. A culture of the pus was positive for B typhosus. Her stools at that time were negative. The infection on the chest wall was very stubborn and drained for about six weeks. It eventually healed solidly and there has been no recurrence in over eighteen months.

WELL, MAKE UP YOUR MIND

A picture of a child playing in the snow appears in *Hygeia* with the caption "Exposure to cold is one of the several factors that are associated with the cause of acute rheumatic fever in young children," while *Neighborhood Health*, published

by the New York City Health Department, carries a picture of three children playing in the snow, with the title "Healthful outdoor play helps build bodily resistance." Further advice is anxiously awaited.

MEDICAL MOTION PICTURES AVAILABLE FOR LOAN

AMERICAN MEDICAL ASSOCIATION

MOTION pictures on various scientific subjects are available on a loan basis. The material falls into two groups:

1. Pictures for medical societies and other scientific organizations,

2. Pictures for the public.

Requests for films should be instituted as far in advance as possible, so that the proper reservations can be made. The exact shipping addresses and dates should be given at the time of the request, also the type of apparatus in which the film is to be run. Responsibility for the projection and care of the film must be borne by the individual or organization which is borrowing it. The American Medical Association does not have projectors available for loan.

The only expense incurred is that of transportation both ways. However, careless handling resulting in serious damage may be charged to the borrower.

A brief description of each film is given in the following list. Notation is made as to the size of the film—16 mm or 35 mm, and silent or sound.

Apply to: Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago, Illinois.

Motion Pictures for Medical Societies and Other Scientific Organizations

Syphilis (A Motion Picture Clinic)—Sound. 35 mm, 9 reels, also 16 mm, 2 large reels, 1,600 ft. each. Running time about 1½ hours.

The diagnosis and treatment of syphilis presented by: Dr. John H. Stokes, diagnosis of early syphilis, Dr. Harold N. Cole, treatment of syphilis, Dr. Paul A. O'Leary, latent syphilis, Dr. James R. McCord, treatment of syphilis in pregnancy, Dr. Philip C. Jeans, congenital syphilis, Dr. Joseph Earle Moore, late manifestations and neurosyphilis. Short talks also given by Dr. Chas. Gordon Heyd, Dr. Morris Fishbein, Dr. Thomas

Parran, and Dr. R. A. Vonderlehr. (Script is available in a 40-page pamphlet, the price is ten cents.)

Audience: medical.

Cancer (Cants Cancer Film)—Silent. 35 mm, 3 reels. Running time about 45 minutes.

A film demonstrating the proliferation of cell tissue and the formation of cancers.

Audience: medical.

Blood Circulation (Harvey Blood Film)—Silent. 35 mm, 3 reels. Running time about 45 minutes.

Audience: medical.

Blood Transfusion—Silent. 16 mm, 1 large reel, 1,200 ft. Running time about 45 minutes.

Three methods of blood transfusion illustrated in detail.

Audience: medical.

Comparative Physiology of Labor—Silent. 16 mm, 4 reels, total about 1,400 feet. Running time about 1 hour.

Demonstration of normal labor in the human, the horse, the cow, the sheep, the dog, the pig, and the rabbit.

Audience: medical.

Effects of Heat and Cold on the Circulation of the Blood—Silent. 16 mm, 1 reel, 300 feet. Running time 12 minutes.

Demonstration of the effect of heat and cold on circulation as seen through a glass chamber installed in a rabbit's ear.

Audience: medical.

Effects of Massage on Circulation of Blood—Silent. 16 mm, 1 reel, 200 feet. Running time 8 minutes.

Demonstration of the effect of massage on circulation as seen through a glass chamber installed in a rabbit's ear.

Audience: medical.

Contraction of Arteries and Arteriovenous Anastomoses—Silent. 16 mm, 1 reel, 250 feet Running time 10 minutes

This film visualizes the contraction of arteries and arteriovenous anastomoses as seen through a glass chamber installed in a rabbit's ear

Audience medical

Therapeutic Exercises for the Shoulder Joint Following Dislocation—Silent 16 mm, 1 reel, 250 feet Running time 10 minutes

Audience medical

Treatment of Compression Fracture of the First Lumbar Vertebrae—Silent 16 mm, 1 reel, 300 feet Running time about 12 minutes

Audience medical

Aids in Muscle Training—Silent. 16 mm, 1 reel, 300 feet Running time about 12 minutes

Demonstration of sling suspension exercises for the upper and lower extremities, graded exercises on a powdered board for the lower extremities, and three kinds of "walkers" for re-education exercises

Audience medical

Underwater Therapy—Silent 16 mm, 1 reel, 400 feet Running time about 16 minutes

Presentation of therapeutic use of large and small exercise pools, Hubbard tanks, and homemade tanks, and demonstration of types of exercises given in cases

such as infantile paralysis, cerebral palsy, and postoperative congenital dislocation of the hip

Audience medical

Occupational Therapy—Silent 16 mm, 1 reel, 300 feet Running time 12 minutes

This film demonstrates occupations to motivate and control the desired physical or mental activity and assist in adjustment to long hospitalization. A section on cerebral palsy is included picturing indirect muscle training

Audience medical

Massage—Silent 16 mm, 1 reel, 100 feet Running time 4 minutes

Audience medical

Motion Pictures for the Public

A New Day—Sound 16 mm, 1 reel, 400 feet Running time about 12 minutes

A dramatized film on the prevention and treatment of pneumonia.

Audience public

Prevention of Burns—Silent. 16 mm, 1/2 reel Running time about 7 minutes

Audience public.

Men of Medicine—Sound 16 mm, 1 reel, 800 feet. Running time about 30 minutes

"The March of Time"—produced by the Editors of Time and Life Released by RKO Radio Pictures

Audience public

"Sir, do you realize to whom you are speaking? I am the daughter of an English peer"

"So what? I'm the son of an American doc"—*Rocky Mt Med J*

Complaining Patient "This liniment makes my arm smart."

Fed-Up Doctor "Rub some of it on your head!"—*Rocky Mt Med J*

Doctor (commenting on lawyer who has just concluded his speech to the jury) "If he had his conscience taken out it would be a minor operation"—*Rocky Mt Med J*

The 68th Annual Meeting of the American Public Health Association will be held in Pittsburgh, Pa., October 17-20, 1939, with headquarters at the William Penn Hotel

THE PHYSICIAN'S INCOME TAX—1939

Prepared by the BUREAU OF LEGAL MEDICINE AND LEGISLATION

THIS discussion relates only to the requirements of the federal income tax law. Information with respect to the requirements of state income tax laws should be obtained from responsible state sources.

The Revenue Act of 1938 amended in numerous respects the prior income tax law, but none of the changes made relate to physicians as a class distinct from the main body of federal income taxpayers.

Every one who is required to make a federal income tax return must do so on or before March 15, unless an extension of time for filing his return has been granted. For cause shown, the collector of internal revenue for the district in which the taxpayer files his return may grant such an extension, on application filed with him by the taxpayer. This application must state fully the causes for the delay. Failure to make a return may subject the taxpayer to a penalty of 25 per cent of the amount of the tax due.

The normal rate of tax on residents of the United States and on all citizens of the United States regardless of their places of residence is 4 per cent on net income in excess of the exemptions and credits.

Who Must File Returns

1 If gross income was less than \$5,000 during 1938, a return must be filed (a) by every unmarried person, and by every married person not living with her husband or his wife, whose net income was \$1,000 or more, and (b) by every married person living with her husband or his wife, whose net income was \$2,500 or more. If the aggregate net income of husband and wife, living together, was \$2,500 or more, each may make a return or the two may unite in a joint return.

2 Returns must be filed by every person whose gross income in 1938 was \$5,000 or more, regardless of the amount

of his net income and of his marital status. If the aggregate gross income of husband and wife, living together, was \$5,000 or more, they must file either a joint return or separate returns, regardless of the amounts of their joint or individual net incomes.

If the status of a taxpayer, so far as it affects the personal exemption or credit for dependents, changed during the year the personal exemption and credit must be apportioned, under rules and regulations prescribed by the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury, in accordance with the number of months before and after such change. For the purpose of such apportionment a fractional part of a month should be disregarded unless it amounts to more than half a month, in which case it is to be considered as a month.

As a matter of courtesy only, blanks for returns are sent to taxpayers by the collectors of internal revenue, without request. Failure to receive a blank does not excuse any one from making a return; the taxpayer should obtain the necessary blank from the local collector of internal revenue.

The following discussion covers only matters relating specifically to physicians. Full information concerning questions of general interest may be obtained from the official return blank and from the collectors of internal revenue.

Gross and Net Incomes What They Are

Gross Income—A physician's gross income is the total amount of money received by him during the year for professional services, regardless of the time when the services were rendered for which the money was paid, plus such money as he has received as profits from investments and speculation and as compensa-

tion and profits from other sources

Net Income—Certain professional expenses and the expenses of carrying on any enterprise in which the physician may be engaged for gain may be subtracted as "deductions" from the gross income, to determine the net income on which the tax is to be paid. An "exemption" is allowed, the amount depending on the taxpayer's marital status during the tax year as stated before. These matters are fully covered in the instructions on the tax return blanks.

Earned Income—In computing the normal tax, but not the surtax, there may be subtracted from net income from all sources an amount equal to 10 per cent of the earned net income, except that the amount so subtracted shall in no case exceed 10 per cent of the net income from all sources. Earned income means professional fees, salaries and wages received as compensation for personal services, as distinguished from receipts from other sources.

The first \$3,000 of a physician's net income from all sources may be regarded under the law as earned net income, whether it was or was not in fact earned within the meaning set forth in the preceding paragraph. Net income in excess of \$3,000 may not be claimed as earned unless it in fact comes within that category. No physician may claim as earned net income any income in excess of \$14,000.

Deductions for Professional Expenses

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The taxpayer should make no claim for the deduction of expenses unless he is prepared to prove the expenditure by competent evidence. So far as practicable, accurate itemized records should be kept of expenses and substantiating evidence should be carefully preserved. The following statement shows what such deductible expenses are and how they are to be computed.

Office Rent—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or

apartment for use as a residence as well as for office purposes, he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in his dwelling house or apartment, he may not, however, deduct any part of the rent of such house or apartment as professional expense, to entitle him to such a deduction he must have an office there, with regular office hours. If a physician owns the building in which his office is located, he cannot charge himself with "rent" and deduct the amount so charged.

Office Maintenance—Expenditures for office maintenance, as for heating, lighting, telephone service, and the services of attendants are deductible.

Supplies—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using, for instance, dressings, clinical thermometers, drugs, and chemicals. Professional journals may be classified as supplies, and the subscription price deducted. Amounts currently expended for books, furniture, and professional instruments and equipment, "the useful life of which is short," generally less than one year, may be deducted, but if such articles have a more or less permanent value, their purchase price is a capital expenditure and is not deductible.

Equipment—Equipment comprises property of a more or less permanent nature. It may ultimately wear out, deteriorate, or become obsolete, but it is not in the ordinary sense of the word "consumed in the using."

The cost of equipment, such as is described above, for professional use, cannot be deducted as expense in the year acquired. Examples of this class of property are automobiles, office furniture, medical, surgical, and laboratory equipment of more or less permanent nature, and instruments and appliances constituting a part of the physician's professional outfit, to be used over a considerable period of time, generally over one year. Books of more or less permanent nature are regarded as equipment and the

purchase price is therefore not deductible.

Although the cost of such equipment is not deductible in the year acquired, nevertheless it may be recovered through depreciation reductions taken year by year over its useful life, as described below.

No hard and fast rule can be laid down as to what part of the cost of equipment is deductible each year as depreciation. The amount depends to some extent on the nature of the property and on the extent and character of its use. The length of its useful life should be the primary consideration. The most that can be done is to suggest certain average or normal rates of depreciation for each of several classes of articles and to leave to the taxpayer the modification of the suggested rates as the circumstances of his particular case may dictate. As fair, normal, or average rates of depreciation the following have been suggested: automobiles, 25 per cent a year, ordinary medical libraries, x ray equipment, physical therapy equipment, electrical sterilizers, surgical instruments, and diagnostic apparatus, 10 per cent a year, office furniture, 5 per cent a year.

The principle governing the determination of all rates of depreciation is that the total amount claimed by the taxpayer as depreciation during the life of the article, plus the salvage value of the article at the end of its useful life, shall not be greater than its purchase price or, if purchased before March, 1913, either its fair market value as of that date or its original cost, whichever may be greater. The physician must in good faith use his best judgment and claim only such allowance for depreciation as the facts justify. The estimate of useful life, on which the rate of depreciation is based, should be carefully considered in his individual case.

In a Treasury Decision, approved February 28, 1934, No. 4422, it is held, among other things, that

1. The cost to be recovered shall be charged off over the useful life of the property,

2. The reasonableness of any claim for depreciation shall be determined on the

conditions known to exist at the end of the period for which the return was made,

3. Where the cost or other basis of the property has been recovered through depreciation or other allowances, no further deduction for depreciation shall be allowed,

4. The burden of proof will rest on the taxpayer to sustain the deduction claimed,

5. The deduction for depreciation in respect to any depreciable property for any taxable year shall be limited to such ratable amount as may reasonably be considered necessary to recover during the remaining life of the property the unrecovered cost or other basis.

Particular attention is called to the last of the foregoing provisions. If, in prior years, rates have been claimed which, if continued, will fully depreciate the cost, less salvage, before the end of its useful life, based on conditions now known, a re-estimate of the remaining useful life should now be made and the portion of the cost that had not been depreciated at the beginning of the year 1938 (for a return for the year 1938) should be spread over this re-estimated life.

Medical Dues—Dues paid to societies of a strictly professional character are deductible. Dues paid to social organizations, even though their membership is limited to physicians, are personal expenses and not deductible.

Postgraduate Study—The Commissioner of Internal Revenue holds that the expense of postgraduate study is not deductible.

Traveling Expenses—Traveling expenses, including amounts paid for transportation, meals, and lodging, necessarily incurred in professional visits to patients, and in attending medical meetings for a professional purpose, are deductible.

Automobiles—Payment for an automobile is a payment for permanent equipment and is not deductible. The cost of operation and repair, and loss through depreciation, are deductible. The cost of operation and repair includes the cost of gasoline, oil, tires, insurance, repairs,

garage rental (when the garage is not owned by the physician), chauffeurs' wages, and the like

Deductible loss through depreciation of an automobile is the actual diminution in value resulting from obsolescence and use and from accidental injury against which the physician is not insured. If depreciation is computed on the basis of the average loss during a series of years, the series must extend over the entire estimated life of the car, not merely over the period in which the car is in the possession of the present taxpayer.

If an automobile is used for professional and also for personal purposes—as when used by the physician partly for recreation, or so used by his family—only so much of the expense as arises out of the use for professional purposes may be deducted. A physician doing an exclusive office practice and using his car merely to go to and from his office cannot deduct depreciation or operating expenses, he is regarded as using his car for his personal convenience and not as a means of gaining a livelihood.

What has been said in respect to automobiles applies with equal force to horses and vehicles and the equipment incident to their use.

Miscellaneous

Contributions to Charitable Organizations—For detailed information with respect to the deductibility of charitable contributions generally, physicians should consult the official return blank or obtain information from the collectors of internal revenue or from other reliable sources. A physician may not, however, deduct as a charitable contribution the value of services rendered an organization operated for charitable purposes.

Social Security Taxes—The excise taxes imposed on employers by section 804, title VIII, and section 901, title IX, of the Social Security Act, commonly referred to as old age and unemployment benefit taxes, are deductible annually by employers in computing net income for federal income tax purposes. If the taxpayer's return is made on a cash basis, as

are the returns of practically all physicians, the taxes are deductible for the year in which they are actually paid. If the return is made on an accrual basis, the taxes are deductible for the year in which they accrue, irrespective of when they are actually paid. Employees, including physicians whose employment brings them within that category, may not deduct the tax imposed on them by section 801, title VIII, of the Social Security Act, generally referred to as the old age benefits tax. If, however, the employer assumes payment of the employee's tax and does not withhold the amount of the tax from the employee's wages, the amount of the tax so assumed may be deducted by the employer, not as a tax paid, but as an ordinary business expense.

Laboratory Expenses—The deductibility of the expenses of establishing and maintaining laboratories is determined by the same principles that determine the deductibility of corresponding professional expenses. Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if they related to a physician's office.

Losses by Fire or Other Causes—Loss of and damage to a physician's equipment by fire, theft, or other cause, not compensated by insurance or otherwise recoverable, may be computed as a business expense and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

Insurance Premiums—Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes, and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise. Under professional equipment is to be included any auto-

mobile belonging to the physician and used for strictly professional purposes

Expense in Defending Malpractice Suits—Expense incurred in the defense of a suit for malpractice is deductible as a business expense.

Sale of Spectacles—Oculists who furnish

spectacles, etc., may charge as income money received from such sales and deduct as an expense the cost of the article sold. Entries on the physician's account books should in such cases show charges for services separate and apart from charges for spectacles, etc.—*J.A.M.A.* Jan 14, 1939

ANNUAL MEETING

1939

On April 24, 25, 26, and 27, 1939, there will be held the 123rd Annual Meeting of the Medical Society of the State of New York. Both the Hotel Syracuse and the Hotel Onondaga will house the various assemblies, the general sessions, and the sections, also scientific and technical exhibits.

The House of Delegates will convene on Monday morning, April 24, in the Hotel Syracuse.

The meeting will last the full four days with the general session on Tuesday afternoon and Thursday afternoon. One half of the sections will hold a morning meeting on Tuesday and an afternoon meeting on Wednesday. The other sections will meet Wednesday and Thursday mornings.

WHAT A LITTLE CARE CAN DO

Eleven thousand fewer people were killed in accidents of all kinds in the United States during 1938 than in 1937—a decline of more than 10 per cent, notes the *Statistical Bulletin* of the Metropolitan Life. Present indications are that the number of deaths resulting from accidental injuries will run around 95 000 in 1938 which figure compares with 106 000 deaths

approximately in 1937 and with 110 000 deaths, the all time high figure in 1936. The 1938 loss was the lowest since the deep depression years of 1932 and 1933 when the number of deaths totaled 89 000 and 91 000 respectively.

Motor vehicle fatalities decreased about 8 000 or from about 40 000 in 1937 to between 31 000 and 32 000 deaths in 1938.

Some of the incurable patients of yesterday are the curable patients of today. It is therefore, reasonable to expect that some of the in

curable patients of today will be the curable patients of tomorrow—E. M. Bluestone, M.D. in *Hospitals*

The Woman's Auxiliary

To the Medical Society of the State of New York

Kings County

A meeting of the Woman's Auxiliary to the Medical Society of the County of Kings was held in the County Society Building on January 17, 1939. The president, Mrs. Milton Bergmann, introduced Dr. John L. Rice, Commissioner of Health, who spoke on "Public Health." Mrs. Mary E. Lewis, president of the National Doll and Toy Collectors Club, exhibited her collection of dolls and spoke on "Doll Collecting and Where It Has Taken Me." Among the guests of the auxiliary was Mrs. Daniel Swan, our State President, who congratulated the auxiliary on the work it has done and on its growth of membership. At the close of the executive session and program tea was served.

Onondaga County

A Membership Tea was held by the Woman's Auxiliary to the Medical Society of the County of Onondaga on January 31, 1939, at the Sedgewick Farm Club. Invitations were extended to all women who are eligible to become members of the auxiliary. The president, Mrs. Winthrop Pennock, welcomed the members and guests.

Dr. William A. Groat, President of the Medical Society of the State of New York, addressed the members of the auxiliary and their guests. On the program for the afternoon was Mrs. Dorothy Kelley Carr who gave a series of recitations.

Mrs. Francis O. Harbach, chairman of arrangements, was assisted by an able committee.

Queens County

Mrs. William Lavelle greeted the members of the Woman's Auxiliary to the Medical Society of the County of Queens at the first meeting held on January 31, 1939. Mrs. Lavelle asked for the cooperation of all the members in the activities of the auxiliary. Chairmen of committees reported that their committees were organized and their work for the year was being planned. Mrs. Robert Yanover, chairman of entertainment, said that final plans had been made for the bridge and tea given on February 8 in the Medical Society Building. The auxiliary enjoyed a film entitled "Eighty Years in Business" given by the Borden Company.

After the meeting a collation was served.

Mrs. George A. Green, 122 South Second Avenue, Mechanicville, N. Y., state chairman of program, has on hand several valuable manuscripts published by the Public Relations Bureau for county chairmen of program who request them. In writing to Mrs. Green, kindly state the date of meeting for which pamphlets are desired.

Headquarters for the Annual Convention of the Woman's Auxiliary to the Medical Society of the State of New York will be in the Hotel Syracuse, Syracuse, New York. Reservations may be made now.

JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA

The William Potter Memorial Lecture will be delivered by M. W. Ireland, M. D., A. M., LL. D., Major General, U. S. Army, Retired, on "Medicine's Debt to the United States Army," at the College Building, 1025 Walnut Street, Philadelphia, Thursday, February 23, at 8:15 P. M.

Medical News

Albany County

Dr Walter E Dandy of the Johns Hopkins Medical School who was to address the Medical Society of the County of Albany on January 25 on "The Diagnosis and Treatment of Lesions of the Cranial Nerves," was taken suddenly ill, and the committee was fortunate to obtain Dr Donald McEachern, Neurologist at McGill University to substitute for Dr Dandy. His subject was Unusual States of Hypotension and Hypertension and Their Treatment."

The new officers for 1939 are president, Dr James S Lyons, vice president, Dr Philip L Forster, secretary, Dr Homer L Nelms, treasurer, Dr Francis E Vosburgh, historian, Dr Charles K Winne, Jr, censors, Dr Otto A Faust, Dr Thomas O Gamble, Dr L Prescott Brown, Dr John J Phelan, and Dr William C Rausch, delegates, Dr Stanley E Alderson, Dr Frederic C Conway, and Dr W Burgess Cornell, alternate delegates, Dr Emerson C Kelly, Dr Raymond G Leddy, and Dr Charles A Perry

Broome County

"Saturday evening January 21, was the scene of the annual dinner of the legislative committee of the Broome County Medical Society, having as guests the Honorable Bert Lord, Representative of the 34th Congressional District, State Senator Roy M Page, and Assemblyman Edward Vincent. Unfortunately, Mr Walters, our other Assemblyman, was ill and could not be with us

"This dinner is primarily intended for a get together and social evening. Same has been held for some years early in the session of the Legislature. Due to the fact that few bills of direct interest to the physicians have been introduced at this time, very little of a legislative nature was undertaken beyond the expression of views on some of our perennial bills which we expect to see introduced soon

The legislative committee of the County Society consists of the Comita Minora, which combination we have found very satisfactory during the few years this policy has been followed "

Clinton County

In a county-wide pneumonia-control program in January, members of the Clinton County Medical Society gave public addresses on the control of pneumonia to fourteen Home Bureau groups

Columbia County

A course on general medicine has been arranged for members of the Columbia County Medical Society for alternate Tuesdays which opened on January 10 and will continue until March 7, at the Hudson City Hospital. Details have been arranged by Dr William S Ladd, Dean of Cornell University Medical College.

On January 10 the subject was "Physiological Interpretation of the Clinical Manifestations in Renal Diseases and Hypertension" The speaker was Dr William Goldring of New York

January 24, the subject was "Practical Endocrinology" The speaker, Dr Samuel H Geist of New York

February 7, the subject was "The Significance of Laboratory Tests and Methods in the Practice of Medicine." The speaker, Dr Ralph G Stillman, New York.

February 21, the subject will be "Dehydration, Acidosis, and Shock" The speaker, Dr Alexander B Gutman, New York.

March 7, the subject will be "Abdominal Pain" The speaker, Dr Edward M Livingston, New York

Dutchess County

Dr Everett D Kiefer, department of Gastro-enterology of the Lahey Clinic, Boston, Mass, was the speaker at a meeting of the Dutchess County Medical

Society on January 11 at St Francis' hospital auditorium

He discussed "Functional Disorders of the Gastrointestinal Tract Colitis—Its Managements and Treatment "

At the December meeting the following officers were elected Dr Scott Lord Smith, president, Dr Gilbert S Tabor, vice-president, Dr L S Stoller, secretary-treasurer, Dr Edgar F Powell and Dr James J Toomey, censors, Dr Aaron Sobel, delegate, Dr Samuel E Appel, alternate delegate, and Mayor Spratt, counselor

Erie County

The Buffalo Academy of Medicine, Section of Pathology, listened on January 25 to a paper on "Non-Caseating Tuberculosis," by Dr Max Pinner, New York City

The Section of Surgery heard on February 1 a paper on "Surgical Treatment of Peptic Ulcer," by Dr Howard K Gray, Mayo Clinic, Rochester, Minn

Greene County

The Medical Society of Greene County met at the Memorial Hospital in Catskill on January 10 Dr George L Branch, newly elected president, presided, and during the absence of Secretary Dr William M Rapp, Dr M H Atkinson acted as secretary A large attendance was present.

Dr Gates, of Coxsackie, gave a short talk on the treatment of pneumonia

Jefferson County

The monthly meeting of the Jefferson County Medical society was held on January 12 at the Black River Valley club Dinner was served at 6 30

Dr Charles M Carpenter, associate professor of bacteriology at the School of Medicine and Dentistry of the University of Rochester, discussed "The Cultural Method of the Diagnosis of Gonococcal Infection " Miss Helen Osterbur, nutritionist of the Jefferson County Tuberculosis and Public Health association, described her work

At 5 P M a tumor conference was held

at the House of the Good Samaritan Cases were presented for discussion

Kings County

The chief features of the program of the Medical Society of the County of Kings on January 17 were

Inaugural Address "Present Day Problems in Medicine," Philip I Nash, M D , F A C P , Brooklyn

Address "The Surgical Treatment of Peptic Ulcer," George P Muller, M D , F A C S , Philadelphia, Pa

Dr William S Collens, Chairman, announces that the Clinical Committee has discussed the problem of making the Friday Afternoon Lecture series as practical and informative as is possible One of the recommendations that has been accepted in line with the plan is to offer a clinical demonstration by the speaker for one-half hour before the scheduled lecture on the subject about which he will speak Ambulatory clinical material will be furnished to the speaker and it is hoped that the speaker will then be able to demonstrate to the members of the audience his own methods of examining the patient and discuss the differential diagnosis during his examination Such clinical demonstrations should furnish concrete examples for the elucidation of the speaker's subsequent dissertation

The program for the month of March is already tentatively arranged and will include such subjects as (1) *Recent Contributions to the Aid of the Cardiac Examination*, (2) *The Clinical Diagnostic Aspects of the Early Diagnosis of Pulmonary Tuberculosis*, (3) *The Diagnostic and Therapeutic Aspects of Subdeltoid Bursitis*

It is also planned that no formal papers will be read and that the talks will be informal If time can be arranged for, it is also likely that questions and discussion will be permitted for approximately ten minutes

If there are any additional suggestions that any member of the Society may have to help to still further improve the Friday Afternoon Lectures, the Clinical Committee will enjoy receiving them

The Doctors' Musical Society of Brooklyn announces these organizations

Doctors' Orchestra—meets Wednesday evenings 47 Flatbush Ave., Brooklyn (Wurlitzer Bldg.), 8 30–11 00 P.M. We need more men and women who can play instruments.

Doctors' Choir—is rehearsing at 614 Eastern Parkway every Friday evening, 8 30 to 11 00. Additional doctors, who can sing, wanted.

Doctors' Theater—the first play, *In slant Relief*, "a satire on Quicures and Quacks is in process of casting—doctors who wish to act may apply

Muscle Lovers—who don't play or sing, may give us their support by joining

For further information communicate with Dr H Tevel Zankel, 614 Eastern Parkway, Brooklyn, PResident 2 3443

The Brooklyn Thoracic Society presented this program on January 20

1 "The Acute Abdomen during Pneumothorax Therapy," Dr Benjamin Burbank, 2 "Mediastinal Flutter," Dr Daniel A. Mulvihill, 3 "Clinical Pathological Conference," Dr Charles Ford Warren

Dr John B D'Albora, president of the Kings County Medical Society last year, was given a dinner at the Waldorf-Astoria, 50th St. and Park Ave., Manhattan, Wednesday, January 25, by the Italian Medical Society of Brooklyn in recognition of his services to the borough and the medical profession

Monroe County

A "highlight" of the dedication of the new home of the Rochester Academy of Medicine was the presentation to Dr Albert D Kaiser, former academy president and chairman of the fund raising drive, of the first Albert David Kaiser medal

The award was in "recognition of community service and outstanding contribution to the Academy of Medicine" Dr David B Jewett, academy president, made the presentation speech

Dr Harry L. Segal and Dr George V

Taplin received the annual academy prizes for original medical theses. Subject of Dr Segal's thesis was "Cigarette Smoke As the Cause of Fatigue and Its Effect on the Electrocardiogram" Dr Taplin's was "Revised Technique for Laboratory Diagnosis, and Control of Serum Therapy in Pneumonia."

Principal speaker at the ceremonies was Dr John F Fulton, physiology professor at Yale University's school of medicine

Dr Fulton paid tribute to Dr George W Goler, retired Rochester health officer, and presented the academy's 20,000 volume library an early volume from the first medical journal, *Miscellanea Curiosa*

Dr William A Groat, President of the State Society, in congratulating the Academy on its enlarged capacity for scientific medical work, took occasion to commend warmly Governor Lehman's use of the scientific approach to insurance questions as recommended in his recent message to the Legislature

Nassau County

Dr Alexander Langmuir, of the state bureau of pneumonia control, visited Nassau County on February 1, 2, and 3, at the invitation of the County Medical Society, and gave twelve illustrated lectures on pneumonia.

New York County

The program of the Medical Society of the County of New York on January 23 included 1 Address of the Retiring President, Dr Clarence Bandler, 2 Inaugural Address of the President, Dr Howard Fox, 3 The Sinister Menace of Narcotic Drugs," Dr Arthur La Roe, President of the American Narcotic Defense Association

The New York Heart Association will hold its annual meeting to be followed by a scientific session, which will be open to physicians and medical students at the New York Academy of Medicine, Room 20, on Tuesday, February 28, at 8 30 P.M. The following program has been arranged "Review of the Year's Activities," Dr

Ernst P Boas, chairman of the association, "Description of the New 'Criteria,'" Dr Harold E B Pardee, "Treatment of Peripheral Vascular Disease," Dr Hugh Montgomery, University of Pennsylvania, Discussion by Dr. Irving S Wright, "The Ballistocardiogram Improvements on and Experience with an Old Physiological Method for Investigating the Heart and Circulation of Man," Dr Isaac Starr, University of Pennsylvania School of Medicine, Discussion by Dr Harry Gold

The annual meetings of the New York Tuberculosis and Health Association and of the Tuberculosis Sanatorium Conference of Metropolitan New York will be held at the Hotel Pennsylvania, New York City, Thursday, March 2. The morning session under the auspices of the Sanatorium Conference, Dr Foster Murray, chairman, presiding, will be held in the hotel's banquet room, starting at 9 30 A M

"The National Health Program" will be discussed at the 12 45 P M luncheon session, held under the auspices of the New York Tuberculosis and Health Association, Dr I Ogden Woodruff, president, presiding. Dr Abel Wolman, president of the American Public Health Association, will discuss the extent and magnitude of the national health program and Dr George Baehr, chairman, Technical Advisory Board, Committee on Neighborhood Health Development, New York City, will give the viewpoint of the practicing physician. Following the luncheon the Board of Directors of the New York Tuberculosis and Health Association will hold its annual meeting.

At the morning session community control of tuberculosis will be discussed. The program of the morning session is as follows. Dr Allan J Hruby, Secretary, Board of Directors, Chicago Municipal Tuberculosis Sanitarium, and Dr H McLeod Riggins, Assistant Visiting Physician, Bellevue Hospital Tuberculosis Service, will talk on "Collapse Therapy in the Control of Tuberculosis," discussion to be led by Dr Herbert R Ed-

wards, head of the Bureau of Tuberculosis of the New York City Health Department. Dr Esmond R Long, director, Henry Phipps Institute of Philadelphia will talk on "Is the Tuberculin Test Worth While in Case Finding?" which will be discussed by Dr Bela Schick, director, Pediatric Division, Seaview Hospital, Dr Robert E Plunkett, General Superintendent of Tuberculosis, New York State Department of Health, and Dr Benjamin S Pollak, Medical Director, Hudson County Tuberculosis Hospital. Tuberculosis statistics for the Metropolitan area of New York for 1933 will be discussed by Godias J Drolet of the New York Tuberculosis and Health Association, and Miss Jessamine S Whitney of the National Tuberculosis Association. At this morning session the Tuberculosis Sanatorium Conference of Metropolitan New York will elect officers for the ensuing year.

For additional information, address Bernard S Coleman, Secretary, Tuberculosis Committee of the New York Tuberculosis and Health Association, 38 Fourth Avenue, New York City. Reservations for the luncheon (\$1 50) should be made before February 25.

Dr Karl M Bowman will speak at 4 30 on February 17 at the New York Academy of Medicine on "The Newer Methods of Treatment of Schizophrenia," and Dr Malcolm F Campbell will speak at 4 30 on February 24 on "Non-tuberculous Urinary Infections."

The program of the stated meeting of the New York Academy of Medicine on March 2 will be a symposium on arthritis. The speakers. Dr Philip S Hench, of Rochester, Minn., Dr Walter Bauer, of Boston, Dr Ralph H Boots. Discussion by Drs Philip D Wilson, Edward F Hartung, and Albert B Ferguson.

Niagara County

Dr Walter L Machemer of Buffalo addressed the Niagara County Medical Society on January 10 in Lockport at the

Tuscarora Club on "The Diagnosis and Treatment of Bowel Obstruction"

Oneida County

Nonprofit medical indemnity insurance was approved by the Oneida County Medical Society at its meeting in Utica on January 10. Dr Herbert N Squier, retiring president of the county society, appointed a committee of ten to work out details on the basis of plans now under way in Monroe, Erie, and Metropolitan counties.

Dr Paul P Gregory, Rome, was elected president of the county body. Others elected vice-president, Dr Frank J Rossi, secretary, Dr James I Farrell, treasurer, Dr Howard D McFarland, librarian, Dr T Wood Clarke, board of censors, Dr William B Roemer, Dr James B Lawler, Dr W C Schuntz, Dr Herbert N Squier and Dr Martin T Powers.

Delegates for two years, Dr William Hale, Jr and Dr Kelley, alternates, two years, Dr Dan Mellen, Dr Arthur F Gaffney, for one year to succeed Dr Kelly, Dr Bradford F Golly.

Dr William B Roemer spoke before the Utica Medical Club when it met with Dr John Gromann on January 12.

His topic was "Zinc Peroxide in the Treatment of Wounds." A social hour and refreshments followed. The club has entered its 48th year. It has a membership of 20.

Orange County

Dr Alexander J Barclay is the new

president of the Newburgh Bay Medical Society, elected at the annual dinner meeting in the Palatine Hotel on January 10. Dr Barclay succeeds Dr John F Mars. Dr Charles E Lane and Dr Leo C. DuBois were re-elected as secretary and treasurer, respectively.

Dr George H Gehrman, medical director of E I du Pont de Nemours, & Co., Inc., was the featured speaker at the meeting and explained the welfare plans of his company in its relation to the employees.

Washington County

The program of the Medical Society of the County of Washington on January 10 included "Foreign Protein Therapy in General Practice," Dr Michael A. Mastrianni, Whitehall, and "Some Problems in Thyroid Disease," Dr George E Beilby, Albany, F.A.C.S., Asst. Surgeon, Albany Hospital, Surgeon, St. Peters Hospital.

Westchester County

Dr W Godfrey Childress, of White Plains, is beginning his second term as president of the Westchester Tuberculosis and Health Association, Inc., after being re-elected to the post at the annual meeting in New York City on January 12.

Edward M. Ames, treasurer for eighteen years, was re-elected, as was James E Bryan, executive secretary of the Westchester County Medical Society who is secretary. Mr Bryan has served the association for three years in this capacity.

REFRIGERATED BLOOD FOR ARMIES

The war clouds hanging over European countries have given an impetus to the study of whether refrigerated, or conserved, blood can be used on a large scale at or near the front. The employment of such blood during the present civil war in Spain has shown that it is an important addition to the resources of the military surgeon. Extensive studies cited in a Paris letter to the *A.M.A. Journal* have shown that blood kept at a temperature of 4 C retains all

its therapeutic qualities for from ten to fifteen days. Refrigerated blood, at least during the first week, resembles so closely fresh blood as to make it safe to use as a substitute. The authors cited the use of refrigerated blood during the civil war in Spain. The government surgeons use a citrated blood whereas in the insurgent armies the whole blood method as advocated by Yudin of Moscow is employed. The results have been equally satisfactory.

Hospital News

Curing the Chaos in Hospital Drug Therapy

A "DEPLORABLE condition" exists in the pharmacies of "the best hospitals in the country," as shown by their own reports, we are informed in a paper* now published in *Hospital Management*, by M S Dooley, M D, and E C Reifstein, M D, of the Department of Pharmacology, Pharmacy of the University Hospital, and the Department of Medicine, College of Medicine, Syracuse University. In fact, they quote another writer as saying that "the shelves of some hospital pharmacies remind one of the exhibits of proprietary medicines in a chain-drug-soda-fountain-lunch-room." They frankly confess that this caustic remark "is well illustrated by our experience in the University Hospital," for "when we reorganized our pharmacy system, we discarded a large proportion from a total of about 1,000 preparations. Those, whether official and otherwise, were not necessarily condemned, although many were poor duplicates of approved preparations and others were harmful or valueless. Only pseudo-science and tradition declared them indispensable."

A World-Wide Condition

Were this a purely local state of affairs, it would not be a problem, but reports from the best hospitals in the country show a similar deplorable condition, we are told. For example, one hospital had 1,500 drugs in stock, another 1,600, others reported removal of 300 to 500 items. Judging from the literature, advertising, and the mass of unworthy, unnecessary drugs imported, this condition is not only world-wide, but is possibly worse elsewhere than in the United States.

The question is, can any hospital staff intelligently prescribe 1,600, 1,500, or even 500 drugs, including diagnostic agents? Although any one member may order only a fraction of them in practice,

as a student and subsequently, he had the ordeal of trying to learn all of them. Experience teaches that he obviously misses adequate knowledge of the few of merit. Such defective and thinly spread teaching about drugs permeates the whole present-day medical curriculum. This kind of thing goes on daily in spite of the fact that there are now many scientific criteria for charting drug actions in the clinic, making it easily possible in most instances to detect poor kinds and qualities of drugs.

Medical responsibility for unreliable preparations remaining in the market needs to be realized if drug therapy is to keep pace with exactness of diagnosis. Notwithstanding the truth of this, the staff member's main contribution to the size and efficacy of hospital drug stocks now, as in the past, is an unchallenged selection of drugs, and there is little realization of the continuing blight on rational therapy resulting from this age-long prerogative.

The Syracuse Plan

Having stated the unenviable status of present-day drug therapy as reflected in pharmacy stocks, we now describe the plan, ten years in operation, based on ward experiences, consultations, staff conferences, pharmacy control, country-wide inquiries, which has obviated, in University Hospital, many of the bad features of the drug problem. While widely gathered information has been helpful, a continued exacting drive on our own drug stock has resulted in the almost exclusive use of drugs of established value. Therapeutic advance, we believe, awaits general adoption of this or some similar plan.

The chairman of the staff pharmacy committee took seriously the admonition to find "a way out of the chaotic drug situation in our hospital." The committee's efforts finally led to publication

* Presented at the 21st Annual Hospital Standardization Conference, New York City, October 17-21, 1938.

of *The Interns Handbook*, which contained, as a major feature, a sharply limited list of drugs rigorously selected because of pharmaceutical adaptability, pharmacologic soundness, and therapeutic usefulness, and using the U.S.P., the N.F., New and Non Official Remedies, Useful Drugs, and pharmacology texts as a basis.

The staff voted adoption of this selection of drugs without serious thought of its effects on prescribing habits, but it is one thing to adopt a drug list, quite another to maintain it, especially in an open-staff hospital. Emotions have played their part in our work. Some staff members having adjusted slowly to a restricted list of drugs, not in hostility but as if it were somebody's "bobby." With prescription pad in hand, the physician is prone to obey time-worn habits and forget a drug list he helped to select. To maintain such a stock in any hospital requires, not the mere setting up of a list and rules, but the constant intelligent vigilance of an outwardly undiscouraged person who must be fairly conversant with pharmacy, able to brush aside pseudo-science, and, above all, to speak the language of the therapist. Indeed it is unsafe to go into the drug market without the pharmacologic and therapeutic knowledge possessed only by a physician. In our work, medical administrative and nursing support has been limited only by our ability to impress our objectives with consideration and clarity.

Medication Simplified

It may be helpful to give some further details of operation and, finally, to suggest some far reaching possibilities, could a similar plan be generally adopted.

The variety of drugs available is determined by the medical director and the pharmacy committee with the aid of the pharmacist, the latter then maintaining

appearance, freshness and potency of stocks, exactness of solutions, titration, sterilization, preservation, and labeling. Although recently the Council on Medical Education and Hospitals, at the initiative of the American Pharmaceutical Association wisely approved full-time pharmacists, this does not qualify pharmacists to select the drugs for hospital needs, a crucial duty, which, if assumed intelligently by physicians, would add greatly to the welfare of patients, quickly reduce the scope, and increase the quality of drugs. Once they come to recognize reliable information about drugs, as about methods of diagnosis, commercial prostitution of drugs will cease.

On this basis, our pharmacy is no longer a vague institution to staff members but is a part of the clinical laboratory system which frees it from serving merely at the dead level of pill counting, dispensing nostrums, specialties, and ready-made proprietaries.

Needless to say, the plan as outlined has strongly influenced the therapy of private patients. These pay for unapproved drugs as purchased on the outside. Excessive costs of such items discourage ill founded medication and stock accumulations. Thus, without coercive intent, an ideal is held before the prescriber.

New drugs present another problem. These are issued as are other unapproved items after the usual reminder, but come at once before the pharmacy committee for review. The service involved is informed of findings as a basis for joint approval or rejection. Pertinent bulletins on these and other drug questions are posted from time to time in the staff room.

It will be seen from this brief outline that medication can be simplified to the advantage of patients and the hospital budget, the essential requisite being a sustained interest of the staff in the careful selection of each drug used.

Surgeon General Thomas Parran in his annual report says: "A greater advance has been made in public health in the United States during the past two years than ever before within a comparable period."

The bulletins issued by the Educational Committee of the Illinois State Medical Society are so good that teachers and hospital directors are asking for copies to give to pupils and patients.

Buffalo's Hospital Scout Troop

A BOY SCOUT troop that does its scouting in a hospital—that is boy scout troop No. 144 of Buffalo, New York. Its locale is the Children's Hospital.

The troop was originated a year ago, reports Moir P. Tanner in *The Modern Hospital*. It has aroused the interest of the boys who are patients, the hospital personnel, and the community. Members of the scout headquarters staff aided in the organization, assisted in the opening meeting, and since then have given their full co-operation to all activities. Thus they have overlooked technicalities regarding age, chiefly because they can visualize the value of scout training to these youngsters. The advantage is not one-sided, however. Discipline of these youngsters has ceased to be a problem.

As they become familiar with the boy scout creed we find the boys in our troop doing their best to be of as little trouble as possible. Their school work has improved immeasurably.

The other day one of the staff doctors said to a lad: "Well, Dickie, you can go home Tuesday." Instead of the expected glee, the doctor saw two large

tears roll down the boy's cheeks as he stammered, "Gee, doc, can't you make it Friday, 'cause scout meeting is on Thursday?"

To many it might appear that a scout would need much wit and ingenuity to find a good turn to do every day in a hospital. But such is not the case. It is amazing how many good turns scout-trained eyes can see to do.

"If you're busy I'll feed Joe," offers a scout as he sees a nurse about to serve a patient who cannot manage alone. Perhaps a comrade is tired and uncomfortable and bored. "I'll read to Pete awhile," offers a scout, alert to do his good turn.

Meetings are held on Thursday nights. Some of the boys wear their scout uniforms and all of them wear scout neckerchiefs. As the meeting opens the colors are raised, the court of honor gives examinations and awards merit badges.

Our scout troop has opened up a new life for these boys. In the future it seems likely that more troops will be located in places in which boys are cared for. For boys who cannot go out into the world of scouting, this greatest of all boys' organizations can come to them!

A Beauty Parlor in the Hospital

TWO YEARS ago a hospital in New York City began to visualize the value of beauty service for its patients as well as for its entire staff. Assuming that there is truth in the statement, "We feel as well as we look," this institution decided to experiment and find out if modern scientific treatment of the hair, skin, and nails would not actually hasten the patient's convalescence and also develop a better morale among the personnel. The decision was reached, says Raymond P. Sloan in *The Modern Hospital*, after a careful examination and study of the attitudes of patients, doctors, nurses, and beauticians.

Doctors admitted that the idea had

possibilities, patients and nurses alike were enthusiastic, a beautician of national reputation was discovered who envisioned in the project opportunities for raising the standards of his profession. So it happened two years ago that Manhattan General Hospital announced a new service, thoroughly modern beauty facilities for patients and employees. Time has brought even stronger conviction that a well organized and carefully supervised beauty salon can and should play a part in the convalescent care of patients in our hospitals today.

Treatments of the skin, scalp, and nails are administered in a suite of eight commodious rooms at Manhattan General

Hospital to those patients who have received the approval of their doctors, also to nurses and other members of the staff. Some of the work is carried on at the bedside, always with the doctors' permission, by operators carefully selected and especially trained. The girls must have a sympathetic nature, present a good appearance, and, most important of all, talk only when spoken to.

Walk down the main corridor on the first floor and turn to the left. The visitor enters a small foyer containing an appointment desk and a glass showcase in which are displayed numerous silver trophies awarded to Adolph, the beautician who eight times has received the national prize for hair dressing and who for three years in succession has won the international prize.

It's a "Real Occasion"

A capital outlay of between \$6,000 and \$7,000 is represented for the equipment. It includes portable machines that may be rolled alongside the bed for facials as well as dryers and lights. Then there are the treatment chairs and other furniture.

With such facilities available, it is not surprising that the patients enjoy the variety of being wheeled down to Adolph's to get "fixed up." It becomes a real occasion to which they look forward, a welcome interruption to hospital routine.

Just as relaxing and beneficial are the treatments given those patients who are confined to their beds. While their bodies are rebuilding, their hair and skin likewise are being properly nourished. Following the call of the young lady attendant, the sanction of the doctor is obtained and an appointment is made. Soon the necessary equipment is rolled up to the bed and the treatment starts—a dry shampoo, perhaps, or a facial or a manicure. As she finishes, the operator takes the machine and gives the patient a light arm and hand massage, which is soothing and relaxing. In consequence, the hair soon regains its luster, the skin takes on the glow of health, and the nails become smooth and strong. Many a doctor confesses that he has to be introduced to his patient all over again. And the patient admits that she feels like a different person.

Newsy Notes

Statistics compiled by the Associated Hospital Service of New York show that the average married woman passes twice as many days each year in a hospital as does her husband. Frank Van Dyk, executive director of the service, reported at a dinner of the American Statistical Association.

Memberships more than doubled during 1938 in the Central New York Hospital Service Corporation, according to reports presented at the annual meeting in Utica. On December 31, 1938, membership numbered 30,090, showing an increase of 18,848 during the year. Seven new district offices were added to make a total of 11, and seven new hospitals which brought their number to 15.

five hospitals in Rochester are asking an advance in the flat rate provided for indigent sick. The hospitals claim indigent sick are carried at a loss of \$1 per patient under present city allowance. The city allows an average of \$4 per day with the cost running to \$5, doctors said.

At a meeting of the Employees Association of the New York State Hospital at Dannemora it was voted to have a bill introduced in the State Legislature to permit employees of the State Hospital to board outside the institution, and to receive in lieu of board the money now deducted from their salaries. Claude Bigelow, president of the Employees Association, said he expected the bill to pass.

Claiming general financial distress,

It was urged at the annual meeting of

the Memorial Hospital of Ithaca that the city take it over "or give us more support"

"The time has come for the city and county to pay their just share of our budget and losses," D A Saperstone, chairman of the credit committee, told them "We're losing money and uncollected accounts are piling up"

Urging definite city support, he pointed out "this hospital can no longer be called a private or even a semiprivate institution We are operating for the good of all our citizens, the same as some of our other city institutions"

. . .

Arrangements for the Jamaica Hospital Circus are rapidly nearing completion, under the leadership of David Ketcham A circus headquarters office has been opened at 90-32 Union Hall St, Jamaica Advance tickets are being sold The circus will play the week of April 17 There will be thirteen complete shows, two daily and three on Saturday Daily matinees will start at 4 P M and the evening performance at 8 15 P M, except Saturday when there will be a special show for children at 10 A M and a matinee at 2 30 P M There will be a boys or girls bicycle awarded at each matinee

The armory on 168th St near Jamaica Ave, will be transformed into an amphitheatre, with a seating capacity of 1,200 for the circus Three rings and two platforms will be used in presenting the performers, many of them making their first appearance after closing winter quarters Other acts, the committee announces, will come from abroad and are making their first American bow

A reduction in rates has been announced by the Hospital Service Corporation of Jefferson County The individual rate will be \$8 a year instead of \$9 and the family rate \$20 instead of \$24

. . .

Because of the abuse of the Medina Memorial Hospital special clinic service

for the poor by persons able to afford regular medical and hospital fees, the medical staff of the hospital has voted to discontinue the clinics, according to an announcement made following the annual staff meeting

. . .

After ninety young women of the Augustana Hospital chorus took their seats at the Sunday Evening club session, the singing director suggested the audience rise and sing "God Send Us Men"—*Chicago Tribune*

. . .

Flying hospitals—speediest and newest of Uncle Sam's medical aids—are maintained at eight air bases along both coastlines and the Gulf of Mexico, according to an article by S R Winters, of Washington, D C, in the February issue of *Hygienia, The Health Magazine*

Twenty-one seaplanes are poised ready to answer medical calls from ships at sea. Aid to injured sailors and passengers and removal of persons from disabled vessels are the usual services they render "NCU," meaning "any Coast Guard unit," is the radio call that summons one of these planes This request for medical assistance is given right-of-way

The idea was first put into practice a few years ago when five seaplanes, known as flying lifeboats, began their task of rescuing human lives out at sea The planes carry a crew of four, and twenty passengers may be accommodated in an emergency They are constructed to make landings on rough seas if necessary Each one is equipped with a collapsible lifeboat and has stretchers for removing the injured from ships The planes are met at their landing field by ambulances to rush the patients to the nearest hospital

In addition to these services the planes endeavor to warn people of impending danger and assist extensively during floods and other disasters by transporting serums and biologic supplies and scouting the afflicted areas for purposes of operation planning

Improvements

The year just closed witnessed nearly a 50 per cent increase in the value of new hospital building projects authorized. Nearly \$149,000,000 of new projects were started, as reported in *The Modern Hospital*, compared with \$103,500,000 for 1937. The 1936 figure was \$96,000,000, in 1935 it was \$41,000,000, and in 1934 only \$39,000,000. So 1938 constitutes the largest post-depression year by a wide margin. Most of the actual construction, of course, will not be completed until some time in 1939 as over \$60,000,000 was authorized in October, November, and December.

Up-to-date figures on the number of beds added are not available at this time but it is doubtful if the increased construction has been sufficient to overcome the deficit piled up during the depression years when construction did not keep pace with growth of population, obsolescence of buildings, and scientific advances in hospital service.

The first therapeutic pool in the Bronx for aftercare of infantile paralysis victims was dedicated in January at Bronx Hospital, 1276 Fulton Ave.

The need of a new main building for the Hudson City Hospital was expressed and plans were revealed for a new addition to the operating room, by Surrogate Robert G. Patne, president of the hospital Board of Trustees, at the annual meeting of the board.

Trustees of St. John's Riverside Hospital are planning to enlarge facilities at the institution within the near future, Dr. Robert H. Shanahan, newly re-elected

president of the board, announced at the annual meeting.

The memory of Peter David Levine, twelve year-old victim of the sensational kidnap murder case, will be perpetuated in the furnishing of a room in the new addition to New Rochelle Hospital by the boy's friends. "This room furnished in memory of Peter D. Levine by his friends," will be the text of a bronze plaque on the door of the room. Marked progress in erection of the extensive addition is being made, the hospital reports. Opening of the new addition is forecast for July 1.

The Leonard Hospital, Troy, has bought the McKean residence, long one of the city's show places, as living quarters for staff members of the hospital. A large living room, reception hall, dining room, and kitchen are contained on the first floor. The second floor has four baths, eight bedrooms, and a large, enclosed sleeping porch.

Mercy Hospital in Buffalo, conducted by the Sisters of Mercy, has installed a new 220,000-volt x-ray machine which cost more than \$10,000. In co-operating in the statewide campaign for the eradication of cancer, the hospital has established a new department of x-ray therapy. The staff is progressing with the establishment of a separate clinic in which early diagnosis of cancer will be stressed. The hospital has a well-equipped laboratory in which specimens can be examined. If necessary, the service will be enlarged and definite days will be specified for tumor cases. Before the new equipment could be installed, an entire section of the hospital building had to be remodeled.

At the Helm

These hospital officials have been chosen:

Dr. Frank H. Herrington, to be chair

man of the medical staff of Horton Memorial Hospital, Middletown.

Dr. J. E. Canfield, to be chief of staff

the Memorial Hospital of Ithaca that the city take it over "or give us more support."

"The time has come for the city and county to pay their just share of our budget and losses," D A Saperstone, chairman of the credit committee, told them "We're losing money and uncollected accounts are piling up"

Urging definite city support, he pointed out "this hospital can no longer be called a private or even a semiprivate institution We are operating for the good of all our citizens, the same as some of our other city institutions"

WARNED IN TIME

["Herr Julius Streicher, addressing a thousand members of the Nazi Welfare Medical Administration at Munich, suggested that Herr Hitler and Signor Mussolini were great because they were non smokers. —News item.]

Tobacco is a noisome weed (Herr Streicher he has said it),

And from its victims there proceed no men of worth and credit,

Though Bismarck puffed, and even snuffed, and kept cigars a-going,

He was a dud—his name is mud on Streicher's latest showing

The men of State, the good and great, avoid those hideous vapours,

Their names appear all bright and clear on History's page and papers

Tobacco jars and fat cigars both fall beneath their veto,

They scorn all types from fags to pipes, like Adolf and Benito

And yet beware—if that bright pair of dictatorial jokers

Now represent the mood and bent achieved by staunch non-smokers,

Why, some may flock to fill, restock their smoking store or larder,

Resolved to miss that doubtful bliss by smoking all the harder

—*Manchester Guardian*

ANALYSIS OF THREE KICKERS

"I cannot understand why so few men attend their county and state medical society meetings. It is not because they are so busy, as the busiest physicians are always found where there is a chance to learn. After years of observation I have reached the conclusion that there are three kinds of physicians who don't attend meetings—(1) the person who has not the ability to plan his work so that he can have an evening for recreation at the meeting, (2) the man who thinks he knows it all, has not read a new book since leaving school, and has no time for reading the JOURNAL or other publications, and (3) the man who is afraid he might lose a patient should he leave his office. These three types form the fault-finding group, they complain, but will not come to the meetings and put their shoulders to the wheel, clarify their visions, help remove the faults they see, and become what is most needed by the society and always welcomed by its officers—workers instead of drones or complainers.

"Yes, the opportunity for the present-day physician to be an up-to-date physician is right at his door, and I am not only sorry for those who are missing these opportunities, but for their patients."—John A. Hawkins, M.D., *Pittsburgh Medical Bulletin*

ELECTROLYSIS ONLY SAFE WAY TO REMOVE HAIR

Electrolysis is the only method for permanent and safe removal of unwanted hairs or abnormal growths of hair on various parts of the body, Anthony C. Cipollaro, M.D., New York, declares in an article published by the Council on Physical Therapy in the *J A M A* for December 31.

It is also the best method for treating many other conditions of the skin. However, it is far

from being a safe procedure in unskilled hands. Carelessness and ignorance when applied to electrolysis may cause injuries to the skin which are objectionable, disfiguring, painful and even, at times, dangerous.

Electrolysis can be used properly only by physicians qualified by training, education and experience and with a thorough knowledge of the anatomy of the skin.

The Women's Medical Society of New York State

TWO meetings a year are held by the Women's Medical Society of New York State, all of whose members must belong to the component county societies of the Medical Society of the State of New York. The next annual meeting will occur in New York City on May 8 and 9, 1939.

The midyear, semiannual meeting was held in New York City January 7 and 8, 1939, conjointly with the New York Infirmary and the Woman's Medical Society of New York City.

On Saturday morning, January 7, there was a Councilors' Meeting in the Board Room of the Lenox Hill Hospital. There was an interesting scientific session at eleven o'clock, followed by luncheon. All women physicians were welcomed.

That evening there was a dinner at the Town Hall Club, in conjunction with the

Woman's Medical Society of New York City. Dr. Kate B. Karpeles and Dr. Elizabeth Kittredge extended the greetings of the American Medical Women's Association. Presidents of several state societies were present. On Sunday, January 8, an afternoon tea for members and their guests was given by the president, Dr. Madge C. L. McGuinness.

The program of the scientific session held on Saturday morning was as follows:

"The Relation of Infant Nurture to Mental Health," by Dr. Margarethe A. Ribble, "Five Year Follow-Up of Fifty Cases of Varicose Veins Treated by Injection," by Frances H. Bogatko, "Difficulties of Parents in Understanding Their Children," by Dr. Mary M. Thomas, "Recent Advances in the Treatment of Pulmonary Tuberculosis," by Dr. Theresa Scanlan.

Officers of the Women's Medical Society

Honorary Presidents

Mary T. Greene, M.D.
Helene J. C. Kuhlmann, M.D.
Rosamie Slaughter Morton, M.D.
Marion Craig Potter, M.D.

President

Madge C. L. McGuinness, M.D.
1211 Madison Ave., N. Y. C.

Vice-Presidents

Kathleen Buck, M.D.
331 Monroe Ave., Rochester
Annie Daniel, M.D.
105 E. 18th St., New York City
Alice Stone Woolley, M.D.
29 B. Hamilton St., Poughkeepsie

Treasurer

Alta Sager Green, M.D.
30 S. Cayuga St., Williamsville

Secretary

Marguerite P. McCarthy, M.D.
102 Caroline Ave., Solway

Councilors

1st District Branch
Isabel Knowlton, M.D.
80 Irving Place, New York City

2nd District Branch

Mary E. Potter, M.D.
305 Washington Ave., Brooklyn

3rd District Branch

Isabella Borden, M.D.
State Education Dept., Albany

4th District Branch

Janet Murray, M.D.
14 Mynderse St., Schenectady

5th District Branch

Clara Pierce, M.D.
137 Harding Pl., Syracuse

6th District Branch

Anna M. Stuart, M.D.
656 Park Pl., Elmira

7th District Branch

M. Louise Hurrell, M.D.
277 Alexander St., Rochester

8th District Branch

Catherine Carvallo, M.D.
391 Jersey St., Buffalo

Honorary Councilors

Helene J. C. Kuhlmann, M.D.
Marion Craig Potter, M.D.
Annetta Parry, M.D.
Maud J. Frye, M.D.
Emily Dunning Barringer, M.D.
Lois L. Gannett, M.D.
Eather Parker, M.D.
Harriet M. Dones, M.D.
Mary Dunning Rose, M.D.
Ethel Doty Brown, M.D.
Rosamie Slaughter Morton, M.D.
Anna H. Vorrhis, M.D.
Daisy M. O. Robinson, M.D.
Louise Beams-Hood, M.D.
Marion S. Morse, M.D.
Mary J. Kazmierczak, M.D.
Clara H. Pierce, M.D.
Elise S. L. Esperance, M.D.

Books

Books for review should be sent to the Book Review Department at 1318 Bedford Avenue, Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

RECEIVED

Internal Medicine Its Theory and Practice in Contributions by American Authors Edited by John H Musser, M D Third edition Quarto of 1,428 pages, illustrated Philadelphia, Lea & Febiger, 1938 Cloth, \$10 00

The Ethology of Trachoma. By Louis A Julanelle Octavo of 248 pages, illustrated New York, The Commonwealth Fund, 1938 Cloth, \$3.25

Biography of the Unborn By Margaret S Gilbert. Octavo of 132 pages, illustrated Baltimore, The Williams & Wilkins Company, 1938 Cloth, \$1 75

The Pneumonias. By Hobart A Reimann, M D Octavo of 381 pages, illustrated Philadelphia, W B Saunders Company, 1938 Cloth, \$5 50

Diseases of the Chest and the Principles of Physical Diagnosis By George W Norris, M D, and H R M Landis, M D Sixth edition Octavo of 1,019 pages, illustrated Philadelphia, W B Saunders Company, 1938 Cloth, \$10 00

A Textbook of Histology Functional Significance of Cells and Intercellular Substances By E V Cowdry Second edition. Quarto of 600 pages, illustrated Philadelphia, Lea & Febiger, 1938 Cloth, \$7 00

Insomnia Its Causes and Treatment. By John A P Millet, M D Duodecimo of 195 pages New York, Greenberg Publisher, 1938 Cloth, \$1 75

The Practice of Medicine. By Jonathan C Meakins, M D Second edition Quarto of 1,413 pages, illustrated St. Louis, The C. V Mosby Company, 1938 Cloth, \$12 50

Big Fleas Have Little Fleas or Who's Who Among the Protozoa By Robert Hegner Quarto of 285 pages, illustrated Baltimore, Williams & Wilkins Co, 1938 Cloth, \$3 00

Plastic Surgery By Arthur J Barsky, M D Octavo of 355 pages, illustrated Philadelphia W B Saunders Company, 1938 Cloth, \$5 75,

REVIEWED

The Radiology of Pulmonary Tuberculosis. By J E Bannen, M B Octavo of 156 pages, illustrated Baltimore, William Wood and Company, 1937 Cloth, \$4 50

In the publication of this volume the author has had a worthwhile purpose, i.e., the inclusion within its pages of the requisites for a knowledge necessary for the proper interpretation of the radiograph of the lungs The contents deal with the technical aspects of roentgenography of the chest, radiologic consideration of the normal and pathologic lung, the pathogenesis, medical and surgical aspects of pulmonary tuberculosis Unfortunately, however, the discussion of these topics is much too brief to serve the purpose

RICHARD A RENDICH

The Infant. A Handbook of Modern Treatment. By Eric Pritchard, M D Octavo of 744 pages, illustrated Baltimore, William Wood & Company, 1938 Cloth, \$6 00

This is "not a textbook or dictionary of treatment," it is rather a handbook for reference. It contains, in almost verbatim report, a series of lectures given by the author at the Infants Hospital, London, of which he was for a number of years medical director

The book covers the treatment of those diseases affecting the infant up to the fifth year of life. It contains a selection of the methods with which the author in his extensive hospital practice has had personal experience and which he believes the best and the most reliable Certain of the measures advocated, the

author properly states are both new and original. Among these, particular mention should be made of the intensive treatment of pulmonary tuberculosis by creosote, the prophylactic use of Koch's old tuberculin for the production of immunity to this infection in young infants, and the treatment of celiac disease without the exclusion of fats from the diet. This book contains much of interest, and it is characterized throughout by originality of thought, keen observation, clear and logical deductions. For these reasons and because of the large clinical experience of the author it is to be expected that this work will receive a cordial reception. It is beyond doubt a most useful, valuable, and modern contribution to pediatric literature.

JOSEPH C. REGAN

The Biology of Arteriosclerosis. By M. C. Winternitz, M.D. R. M. Thomas, M.D. and P. M. LeCompte, M.D. Octavo of 139 pages, illustrated. Springfield, Charles C. Thomas, 1938. Cloth \$4.00.

The authors of this monograph hope to establish a better foundation on which to base future study of vascular diseases. By the use of the long known methods of injection and tissue clearing they have worked out the pattern of the origin and distribution of blood vessels in the walls of the arteries. He correlates the gross and microscopic changes in blood vessels, demonstrates that tissue changes here are by no means different from that found elsewhere in the body, and decries the term "degeneration" as applied to arteriosclerosis.

SAM P. BAILEY

Symptoms of Visceral Disease. A Study of the Vegetative Nervous System in Its Relationship to Clinical Medicine. By Francis M. Pottenger, M.D. Fifth edition. Octavo of 442 pages, illustrated. St. Louis, The C. V. Mosby Company 1938. Cloth \$5.00.

This is the fifth edition of a work that first appeared in 1919. Dr. Pottenger was among the first to grasp the significance of the implications of the autonomic nervous system in medicine in general.

He has kept pace with the various contributions made during the past two decades.

His book is an excellent summary of the various conditions in which the autonomic nervous system is involved. There are thirty six chapters in the book each dealing with a particular phase of the subject. Numerous illustrations clarify the subject matter. The many references at the end of each chapter will prove a guide to the progressive doctor whenever he desires further information on any particular subject.

While interest in the autonomic nervous system has been aroused in late years because of surgical method of treatment introduced in such subjects as angina, hypertension, and peripheral vascular disease, the medical implications are too numerous to mention. For this reason the book is particularly recommended, as it covers the subject adequately, and is written in a clear and concise manner.

It is highly recommended to those who desire to keep abreast with the fundamental contributions to medicine.

IRVING J. SANDS

Diseases of the Thyroid, Parathyroids, and Thymus. By André Crotti, M.D. Third edition, thoroughly revised and enlarged. Quarto of 1,229 pages, illustrated. Philadelphia, Lea & Febiger 1938. Cloth \$20.00.

This is a thoroughly revised and enlarged third edition with 262 illustrations, thirty-nine plates in color and 1,092 pages of text. The material encompassed in this volume is based on a large personal experience in the surgical and medical treatment of goiters. There are fifty-one chapters which treat of the anatomy, physiology, chemistry, interrelations, pathology and clinical symptoms of the various types of goiter. One extensive chapter treats on the author's research work on the causes of goiter. The medical treatment of simple goiter is considered and the indications for operation in and the manifestations of thyrotoxicosis are considered in detail. The final chapters are concerned with the anatomy, chemistry, interrelation, pathology, and tumors

of the thymus gland. The numerous illustrations are well chosen. The text is unusually readable and the work of others in the field of goiter is discussed together with the author's own experiences. A voluminous bibliography is appended together with a large author and subject index. The volume is recommended to the general surgeon who wishes to perfect himself in the treatment of goiter and especially to the surgeon primarily interested in goiter. The volume is unusually comprehensive.

EMIL GOETSCH

Diseases of Women. By Ten Teachers under the Direction of Clifford White, M.D. Edited by Sir Comyns Berkeley, Clifford White, and Frank Cook. Sixth edition. Octavo of 492 pages, illustrated. Baltimore, William Wood and Company, 1938. Cloth, \$6.00.

This book is well known to the medical profession of England and the United States. The authors have such high standing in the gynecologic specialty in England that their work would be authoritative in any event.

This latest and sixth edition has been thoroughly revised and brought up to date. Especial emphasis may be laid on the excellent chapter on the physiology of menstruation, and the latest theories of the relation of menstruation and the endocrines.

All phases of diseases of women are covered in the volume, and a short paragraph at the end of each chapter gives the latest and most approved form of treatment.

The book is not a textbook on operative gynecology, but the usual gynecologic operations are clearly described.

As a textbook, and as a reference, this work will be an addition to the library of all those who are interested in this specialty.

WILLIAM SIDNEY SMITH

The Life of Chevalier Jackson. An Autobiography. Octavo of 229 pages, illustrated. New York, The Macmillan Company, 1938. Cloth, \$3.50.

We have pondered for many days in attempting to put down in words our impressions and reactions to a wonderful story of an illustrious man and famous physician.

In order to do justice to the author and his story, a review should really be a copy of the entire book. Dr. Chevalier Jackson sets a remarkable precedent as an author, as one follows with intense interest the unfolding of a life so rich and full in the manifold accomplishments and benefits to humanity. Fascinating indeed is the story of the life of Chevalier Jackson from his ancestry through the decades to maturity when the great edifice of accomplishments was so firmly constructed on a foundation built of material—hard work closely cemented by the sweetness and gentility of character molded by heritage, training, and study.

To the layman *The Life of Chevalier Jackson* is a novel classed with the best, to the physician, not only is this fruitful life a story but a pattern on which many have tried to mold, to the bronchoscopist, the author actually steps out of print and is viewed with respect and love, as the reader sees the master himself traveling hundreds of miles to lecture and teach his fellow physicians and thus all for the glory and welfare of man—the patient.

SAMUEL ZWERLING

ORDERING BOOKS

As a service to our readers, books listed in this issue or any other medical book in print may be ordered through T. H. McKenna, Inc., 878 Lexington Avenue, New York City. Phone BUtterfield 8-6603.

NEW YORK STATE JOURNAL *of* MEDICINE

VOLUME 89

MARCH 1 1939

NUMBER 5

Editorial

Support the Lien Act

The Hanley-Mauller Act gives physicians no more than the vast majority of honest people would agree that they are entitled to receive. The lien bill does not guarantee payment for *all* emergency care or *all* treatment to victims of accidents. It merely gives the profession a means of collecting its bills when the patient actually receives cash to pay for medical and other expense connected with his injuries.

Awards for personal injuries are computed largely on the basis of medical expenditures and loss of income occasioned by the accident. There is no justification for failure to pay doctor bills when damages are granted, yet this is a common occurrence.

When a physician is summoned to attend an accident case, he does not stop to inquire into the patient's ability to pay. Very often, after he has given his service, he finds there is no likelihood of ever collecting a fee. All the more reason why payment of the doctor should be assured when the patient actually receives money for this purpose.

The law protects hospitals and lawyers against chisellers by granting them a lien on damage awards. The Hanley-Mauller Bill confers similar protection on physicians. Obviously the services of the latter are entitled to the same safeguards as attorneys' and hospitals'.

In the past few years physicians' lien bills similar to the pending one have failed of adoption in spite of the obvious justice of their provisions. The Legislature, like many patients, sees no need to hurry where the payment of doctors is concerned. There is much favorable sentiment for this legislation, however, and the Hanley-

Mailler Act stands a good chance if enough physicians get behind it and show they are behind it by letters, telegrams, and telephone calls to their representatives in Albany

Some Legal Facts

Physicians of all political complexions are agreed in condemning the pending monopoly suit against the A M A. There is a general conviction, even among opponents of A M A policy, that this action is nothing other than a club to force the profession to accept compulsory health insurance.

In these circumstances the profession has no doubts of the ethical strength of its position. To many physicians who are wondering about its legal status, an article in the *Fordham Law Review* offers some enlightening facts. First of all, the article in question casts serious doubts on whether the practice of medicine comes within the purview of the antitrust laws. The Clayton Act specifically states that labor is not a commodity and reserves for it the right to organize for mutual help and assistance. In a case squarely in point, the courts have held that medical service is labor rather than a commodity. It does not seem, therefore, that medical practice comes within the scope of the antitrust laws, or that medical organization, any more than labor organization, can be considered in restraint of trade. This point of view is strengthened by the fact that the administration of medical care is a local and not an interstate act.

There are also explicit court decisions on the right of a medical organization to discipline members who violate its rules. "It has very constantly been held that the rules and bylaws are an agreement which (the member) expressly or impliedly accepts, and by which he agrees to govern his professional conduct. A society's only means of keeping erring members in line are censure, suspension, and expulsion. These weapons are legally recognized checks on straying members."

An extremely interesting and important feature of the article quoted is its disagreement with a recent decision of Justice Bailey in the United States District Court. Justice Bailey held that the Group Health Association of Washington, D C, is not practicing medicine. According to the writer in the *Fordham Law Review*, since the corporation, through its agents, gives medical treatments, it is in effect practicing medicine, for "it is generally recognized that a licensed practitioner of a profession cannot practice his profession as an employee of an unlicensed person or corporation, and if he does so the unlicensed person or corporation is guilty of practicing

that profession " The law does not divide the practice of a profession "into departments, on one side the actual performance of the professional services, and on the other, the business side." If the courts adopt Justice Bailey's ruling it will lay all professions, not merely medicine, open to the grossest form of commercial exploitation

As a matter of fact, the nonmedical implications of the case against the A M A are disturbing thoughtful persons in all fields. If the government wins its suit against the A M A, not only will corporations be empowered to invade the professions, but the scope of the antitrust laws will be broadened to include almost every type of contract and every form of business and professional relationship. The Department of Justice will exercise virtually unlimited power over American business and professional life.

A hint of what might lie ahead is found in Assistant Attorney General Thurman Arnold's pronouncements on the monopolistic aspects of advertising. Even more illuminating is his willingness, in the case against the A M A, to accept a consent decree "in the event that voluntary co operation results in constructive proposals *going far beyond the elimination of illegal practices* " As an editorial in *America's Future* observes, ' this is government by blackjack. It substitutes Thurman Arnold for the Congress of the United States ' "

The outcome of the Administration's action against the A.M.A. is of prime importance to the entire people of this country, to industry and the other professions no less than to medicine. As the *Fordham Law Review* article concludes, a decision adverse to the A.M.A. would radically upset all our concepts of the purpose and scope of antitrust legislation and alter the whole structure of industrial and professional relations with the public and the state.

Herpes from Vitamin B₁

The public in general has become "vitamin-minded." What with all the proud advertising claims of cough drops, candies, and even beer, vitamins are being consumed by the carload in the belief that only benefit can be derived from their use. It is inconceivable that the vitamins, which are necessary in definite amounts for the maintenance of health and when deficient produce disease, do not also produce toxic phenomena when overabundantly present in the human body. Therefore, the report of Steinberg's¹ observations on the untoward effects resulting from the use of large doses of vitamin B₁ is a timely one.

¹ Steinberg C. L. *Am. J. Digestive Diseases* 8: 630 (Dec.) 1933.

He has treated over 300 cases of chronic arthritis with various preparations of vitamin B complex together with vitamin B₁, and in three of this number herpes zoster occurred during the course of treatment. That vitamin B₁ was the sole responsible factor was evident from the fact that in one patient herpes was made to recur upon resumption of the vitamin therapy. In other instances, Steinberg noted symptoms suggestive of smooth muscle spasm. These findings strongly suggest that unusually large doses of vitamin B₁ may produce an irritation of the peripheral nerve plates.

Clinically one should suspect such irritation when the patient begins to complain of burning pain in some portion of the skin. The use of the vitamin should be stopped, and after a period of time resumed only in smaller amounts.

Vitamin therapy, like all other forms of medication, requires medical supervision. Their use for self-medication should be restricted since an adequate diet furnishes the amounts necessary for normal metabolic activity. The need for supplemental vitamin dosage indicates a disturbance of metabolism which only a doctor can detect and manage properly.

Sulfapyridine

Since the establishment of the efficacy of sulfanilamide in the control of streptococcus infections, biochemists have been hard at work to find a chemical preparation which would be equally effective in the pneumonias. Sulfanilamide itself has been found to have favorable action on Type III pneumonia.¹ Both bacteriostatic and bactericidal effects have also been reported on Types I, II, and IV.^{2,3} From clinical observations, it appears that in the chrysoidin compounds we have a drug capable of controlling pneumonia.

Recently, sulfanilamide and pyridine have been synthesized and the resultant compound is known in England as Dagenan, here as sulfapyridine. The early investigations yielded promising results but unfortunately the cases of pneumonia subjected to this treatment were not typed. More has since been learned concerning the effectiveness and toxicity of sulfapyridine in various types of pneumonias.^{4,5} Dramatic clinical results have been reported, but the use of the chemical seems to be attended with marked gastric discomfort even though it is about one-fourth as toxic as sulfanilamide.

1 Sadusk, *New Eng. J. Med.*, **219**, 787 (1938)

2 Britton, *Brit. J. Exp. Path.*, **19**, 140 (1938)

3 Rosenthal, *U. S. Pub. H. Ser. Reports*, **37**, 205 (1937)

4 Wein, *Quint. J. Pharmacy and Pharmacology*, **11**, 217 (1938)

5 Whitby, *Lancet*, **1**, 1,210 (1938)

At the present time, intensive studies are under way in all medical centers and, pending authoritative reports, sulfapyridine will not be available for general use. Studies of its value both in comparison to serum therapy and in conjunction with it are awaited.

Current Comment

"Politics, politics and more politics would be the rule of each and every official and department of any federal or state organization, if compulsory health insurance is made a reality." Dr Clyde P. Dyer, writing in the St. Louis County Medical Society *Bulletin*, February 3, 1939

"If people generally would visualize medical societies as groups composed of their own personal physicians, there would in most instances be no need for further assurance that the interests of patients will always remain their first consideration

"Improved methods are needed in distributing medical care and no one realizes more fully than doctors themselves the peculiar requirements for providing adequate medical service." From the *Pittsburgh Medical Bulletin* in a recent issue

"There are many kinds of success (in medicine) and no one winner, and perhaps it is not so much where you come in as how you ran that matters." Dr Robert Hutchison, president of the Royal College of Physicians of London recently quoted in *Medical Record*

'A people thoroughly informed is a people armed against tyranny' said Mr Robert Lund at the recent meeting of the National Association of Manufacturers. While theoretically, knowledge

is power, the informed scientist as well as the educated proletariat may find themselves at a disadvantage before a well implemented group of politicians. The surest protection for the institution and practice of medicine is an informed public opinion. We believe a great deal more time, money and energy must be spent to acquire an enlightened and favorable public opinion at least for medicine. For public opinion, if not openly hostile at the moment, is at least inimical

"For this situation we have ourselves largely to blame. Medicine has not at any time courted public opinion. It has been secretive and reticent as to its aims and purposes. And people fear the thing they do not understand. The measure of our stupidity as physicians is our failure to educate the public to an understanding of the aims of medicine. The outlook for a reasonable and controlled public educational policy for medicine seems bright. As far as we can see, the only stumbling block is the physicians." The foregoing is from an editorial "The Public Will Decide," which we found difficult not to reproduce in its entirety. It may be found in the February *Westchester Medical Bulletin*

"To indulge in an immense new outlay of funds for public health such as can be financed only by depriving people of needed housing, food, and clothing is to apply merely palliative methods while aggravating the real causes of the malady." S. Q. Laplus, in the *Westchester Medical Bulletin* of recent date

TOPICAL APPLICATION OF VITAMIN A

Efficiency Judged by Growth Stimulation

WALTER H EDDY, Ph D , and JOAN L HOWELL, New York City

(From the Laboratory of Physiological Chemistry, Teachers College, Columbia University)

IT is generally agreed that vitamin D may be absorbed through the skin and function in the correction of rickets when so administered. The question of vitamin A absorption is not so clearly demonstrated and the following tests were conducted to obtain definite evidence on this point.

Six series of tests are reported conducted at different time intervals during 1937 and 1938. In each series the rats used were first depleted of vitamin A by use of the U S P basal diet and started on the test only when the weight was less than, or equal to, that of seven days previous. In the topical applications, hair was removed from the back of the neck of the rat by clipping to expose an area of about one square centimeter, clipping done with care not to break the skin. The vitamin product was rubbed into the skin of this area and allowed to remain for a specified number of minutes (four minutes in all but the first series). During this period the rat was held and prevented from reaching the area with either front or hind paws. Before it was released the incision was washed off with soap and water.

Applications by mouth or incision were made daily for twenty-eight days following depletion.

Experimental Data

Series I In this preliminary study six rats were used to determine the relative effect of two-, four-, and six-minute topical applications daily. In this series 2 of the rats failed to show any growth response and died of A deficiency. One showed a delayed response. A beta-carotene emulsion in a cocoa-butter base was used in this series.

Since in this series no advantage appeared from the longer period of application, we standardized succeeding tests at four minutes daily for topical application.

Series II In this series we contrasted the effect of feeding 0.24 mg beta-carotene emulsion in cocoa-butter daily with the same amount topically applied daily in the manner described in Series I (four-minute application). This amount of emulsion assayed 6 U S P units of vitamin A. The following were the results obtained.

The behavior of the "rubbed" group in this series showed conclusively that the vitamin A applied as beta-carotene emulsion topically did induce growth stimulation and must have been absorbed. The same amount by mouth induced greater growth effect, the ratio of body weight gain being 46.5/26.1.

TABLE SERIES I

In a feeding test run at the same time with 2 mg USP Reference Oil daily, we got the following gains 70, 62, 49, 49, 48, 48, 42, 34. Average for rats making 12 to 60 grams gain 45 grams. This indicated that we had actually fed 6 USP units daily in the 0.24 mg of the beta-carotene emulsion.

In the same period we got the following gains with 0.6 mg of USP Reference Oil daily 31, 31, 31, 26, 24, 23, 20, 20. Average 26 grams. From the growth response of the "rubbed" rats (average 26 grams) it would follow that the topical application of 6 units of beta-carotene A emulsion daily produced the growth effect of 1.8 USP units of vitamin A fed by mouth in form of USP Reference Oil. The ratio of 6/1.8 = 3.3. On this basis of comparison, the topical application was one third as efficient in growth stimulation as when the same amount of A source was fed by mouth.

Series III—This series was run to determine whether beta carotene in na-

tural waxes behaved the same as beta-carotene in cocoa-butter, the product being available in both forms. The test results were as follows:

From the viewpoint of the objective of the series it was evident that with natural waxes as emulsifier, the beta-carotene by mouth or inunction behaved quite as efficiently as in cocoa-butter. The series again demonstrated that for growth effect, feeding was more efficient than inunction, but that the topically applied vitamin was absorbed.

Series IV—In this series we repeated the test of beta-carotene but with the natural waxes as emulsifier. The results as affecting growth response are shown in the table below.

In this series again, feeding produced better growth than did inunction.

To determine the effect on the skin itself, we selected the following rats, removed a layer of skin from the back of the neck of each, and made a histologic study of sections of these skins. Rats

45813m and 45726f were killed on depletion to serve as *controls*, and to determine the degree of A deficiency in the skin at that time. Presumably, this represented the condition of all the rats at the end of the depletion period.

From the "rubbed" rats we selected 45551m, 45608f, and 45397f as representing rats which by growth response (47, 18, 22 grams, respectively, in 28 days) showed variation from good to low response. The 2 "fed" rats, 45381m and 45609f, were used. They differed also in growth response (64 and 23 grams, respectively). Rats 46142f and 46029f were rubbed with the waxes used in emulsifying beta-carotene, but not with carotene. As they lived through depletion, and twenty-eight days after, they represented still more severe deficiency than rats 45813m and 45726f, having been sixty-four and seventy-two days on an A-free diet.

Rat 45245m was added as a rat on the basal A-free diet only that had lived sixty-three days.

TABLE SERIES IV B

| RATE | DEGREE OF SEVERITY OF AVITAMINOSIS A | METHOD OF APPLICATION OF A | WEIGHT GAIN IN 28 DAYS Gm. | UNITS A APPLIED DAILY | AUTOPSY FINDINGS |
|--------|---|----------------------------------|--|--------------------------------|---------------------------------|
| 45551m | Least (1) | Rubbed | 47 | 6 | No pus |
| 45608f | 2 | Rubbed | 18 | 6 | Pus in tongue |
| 45597f | 4 | Rubbed | 2 | 6 | Pus in tongue and ears |
| 45581m | 3 | Fed | 64 | 6 | No pus |
| 45609f | 8 | Fed | 23 | 6 | No pus |
| 45513m | 6 | 33 days depletion | | 0 | Pus in tongue |
| 45726f | 7 | 39 days depletion | | 0 | Rt. eye badly affected |
| 45629f | 8 | Solvents | +20 | 0 | Both eyes badly affected |
| 45142f | 9 | Solvents | -21 | 0 | Both eyes, and pus in tongue |
| 45245m | 10 most severe | 53 days depletion | -81 | 0 | Pus in tongue ears and left eye |

The above summary gives the outstanding features of the comparison

These results show that, in general, the skin in the rubbed area showed better recovery from depletion than skin from the same area in the fed rats with one exception. Also that in a group the rats gaining most weight showed best recovery.

Series V—Carotene vs. Fish Oil A Absorption. In this series we contrasted the absorption of topically applied carotene vs fed carotene, with the absorption of similarly applied Fish Liver Oil A. The carotene used was beta-carotene emulsion in natural waxes of the American Chlorophyll Co. The A used was that of the American Research Products, 12 mg of the beta-carotene emulsion and 0.15 mg of A.R.P.I's A were used (equivalent to 30 U.S.P. units A) daily

These results indicate that both carotene and vitamin A were absorbable by

CHART 2 Contrast in the growth effect of carotene and fish oil vitamin A ester when fed by mouth and applied by inunction.

intact rat skin in sufficient amount to stimulate growth, but that the carotene was better absorbed than vitamin A is also indicated in this test.

That this was not due to difference of a unitage in the sources applied, is shown by the similar effect of the two sources when fed

EXAMINATIONS—AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

Application for admission to the Group A, May, 1939, Board examinations must be on file in the Secretary's Office not later than March 15, 1939

The general oral, clinical, and pathologic examinations for all candidates; Part II Examinations (Groups A and B), will be conducted by the entire Board, meeting in St. Louis, Missouri, on May 15 and 16, 1939, immediately prior to the annual meeting of the American Medical Association. Notice of time and place of these examinations will be forwarded to all candidates well in advance of the examination dates.

Candidates for re-examination in Part II (Groups A and B), must request such re-examina-

tion by writing the Secretary's Office before April 1, 1939. Candidates who are required to take re-examinations must do so before the expiration of three years from the date of their first examination.

The annual dinner meeting of the Board to which all diplomats and candidates are invited, as well as their wives and others interested in the work of the Board, will be held at the Congress Hotel, St. Louis, on Wednesday evening, May 17, following the close of the examinations.

Application blanks and booklets of information may be obtained from Dr. Paul Titus, Secretary, 1015 Highland Building, Pittsburgh, Pennsylvania.

MEDICO-MILITARY PREPAREDNESS EXHIBIT

On Monday, April 10, 1939, there will be held at the Seventy-First Regiment Armory, in New York City, the second exhibit on Medico-Military Preparedness. This exhibit is being prepared under the auspices of the medical officers of the organized reserve of the metropolitan area. The committee in charge consists of Lt. Col. Edgar W. White, Col. Harry C. Saunders, secretary, and Col. John L. Kantor, chairman.

Among the exhibits shown by the regular army last year was the experimental four-wheel drive ambulance which can climb a forty-five degree grade with ease in rainy weather, the new ambulance body invented by the Research Laboratory at Carlisle Barracks, convertible so as to carry easily four litter cases or five ambulatory cases, an airplane crash outfit, and an arctic rescue unit. These contributions were demonstrated by regular army officers detailed from the Medical Field Service School at Carlisle Barracks, Pa. There will be a similar display this year.

The original exhibits made by reserve officers

included training planes of typical units and installations, administrative charts, tables, diagrams, models, sanitary installations, and war problems with their solutions. An interesting group of demonstrations illustrated the progress of a wounded soldier from the front line to the General Hospital in the rear. These items were prepared by medical, dental, and medical administrative officers of the Reserve Corps.

This year the exhibits by this group of officers promise to be still more numerous, interesting, and instructive. It is planned to have entirely novel presentations by veterinary and chemical warfare (gas) officers. The coming exhibit will be publicized so that not only all reserve officers but all National Guard officers and officers of the regular army stationed in the metropolitan area will be invited to attend. In addition, the exhibit will be open, as it was last year, to the entire medical, dental, and veterinary professions, to medical students and nurses, and to the general public. No tickets of admission will be required.

AFTERPAINS

STUART B. BLAKELY, M.D., Binghamton, New York

LOWER abdominal pains after labor caused by intermittent uterine contractions are called "afterpains." Under the term "tranchees," French obstetricians have written of them in considerable detail. They are intermittent, are associated with visible and palpable uterine contractions as evidenced by hardening, rounding, and elevation of that organ, and are localized in the lower abdomen and (occasionally) the upper thighs, but rarely—possibly never—felt in the sacral area. It is not necessary to labor the point that they are caused by uterine contractions. In genesis and character they are like first stage labor pains, though usually of longer duration.

A study was made of 50 puerperal patients who recorded 1,529 afterpains—there were probably more. On the average, they began between five and six hours postpartum. Afterpains rarely begin immediately after labor, a patient's complaint of lower abdominal pain at that time should, until proved otherwise, be considered under some other and occasionally a more serious diagnosis. Their frequency was absolutely irregular, ranging from a few minutes to hours. It would seem that pain does not accompany every postpartum uterine contraction. The duration of the greatest number was between one and three minutes. Fifteen per cent lasted less than one minute (over half of this figure was furnished by 3 patients), 4 per cent lasted ten minutes or more, in 2 cases over thirty minutes. They rarely continued beyond forty-eight hours. A good yardstick for their severity is not at hand.

Afterpains vary from a vague discomfort to an unnerving agony, severe enough to induce even vomiting and shock. Not only do patients themselves present great variations in psychic reaction to pain in

general, but uteri, also, exhibit a wide range of sensitiveness and reaction to local and other stimuli—something not easily explained by such ignorance concealing terms as 'pain threshold' and 'adequate stimuli.' The fundus is the most sensitive part of the uterus and sometimes the slightest touch upon it provokes or augments afterpains. Less frequently, irritation anywhere in the genital tract, a full bowel or bladder, the taking of food or drink, or even turning in bed are initiating causes.

Afterpains are frequently started or made worse by suckling or any stimulation of the nipple. In some patients they occur only at that time, and are occasionally severe enough to make the woman dread or even refuse to nurse.

Afterpains are stated to be favored by exaggerated uterine distension, as after twins or polyhydramnios, long difficult labor, rapid labor with hard pains, premature separation of the placenta, large placenta, uterine atony (?), foreign body in the uterus, slight infection of the uterus (any infection more than slight stops them particularly streptococcal).

Finally, afterpains are rare in primiparae, but almost the rule in multiparae. This fact has been expressed by two axioms: (1) the greater the parity, the greater the pains; (2) a diagnosis of afterpains in a primipara is always doubtful—statements essentially though not entirely true. On close questioning a fair percentage of primiparae will admit to at least some lower abdominal discomfort for the first day or two postpartum caused by uterine contractions, which they ascribe to 'gas' or some mysterious 'normal' postpartum process. Multiparae occasionally suffer a great deal of pain after some of their labors, after others little or none at all. One X para claimed that

she had never had any pain after any of her babies. The causal factors in these variations are not easily identified. It is, however, entirely true that severe afterpains are rare in primiparae.

The foregoing comprises nearly all that is definitely known about the subject under discussion, i.e., afterpains. Two points are of outstanding interest: (1) the relation between nipple stimulation and afterpains, (2) the frequency of afterpains in multiparae, in contrast with their relative rarity in primiparae. Were these two satisfactorily explained, afterpains would present far less mystery. Thirty-three years ago Joseph Halban¹⁰ wrote a remarkable paper bearing on one of these problems under the title "The Internal Secretion of the Ovary and Placenta and Its Significance for the Function of the Mammary Gland." It was almost prophetic, and the result of pure clinical observation and inductive reasoning. Few can hope to even approach the extent and thoroughness of his investigations or the brilliance of his logic. That article is still distinctly worth reading. The writer of the present paper wishes to subject the old accepted theories about the two phenomena above mentioned to a critical examination, and, on the basis of the study of the scanty literature and an analysis of afterpains occurring in 50 patients, to offer a more reasoned explanation for their occurrence. By no means does he claim to have all the answers, or to know all the factors involved. One of the most common, but obscure and neglected, postpartum complaints merits some study and thought. The conclusions must be somewhat speculative and not completely susceptible to scientific proof. This weakness is inherent in the nature of the subject.

Nipple Stimulation and Afterpains

To properly approach the first problem, i.e., the relation between nipple stimulation and afterpains, it is necessary to speak briefly of the modern and intriguing theories of lactation.^{5,19,20,26} The obstetrician is familiar with three

physiologic phenomena of the breasts and nipples.

1 The growth and development of the breasts during pregnancy. Estrin, produced by the placenta, provides the stimulus. This hormone is believed also to inhibit the pituitary (and possibly the breasts directly), and to sensitize the uterine muscle to "oxytocin," a general term applied to postpituitary secretion or other uterine stimulating substance. With the expulsion of the placenta the high level of blood estrin falls rapidly, and its restraining action on the pituitary ceases.

2 Lactation. Suckling causes the flow of milk from the breasts, if nursing stops, milk secretion also stops. There is ample experimental and clinical evidence that this action, both centripetal and centrifugal, is hormonal and not a nervous reflex.^{2,3,8,24,26,28,29} Nipple stimulation produces in the breast tissue a hormone, still hypothetical, that is carried by the blood to the anterior pituitary. Acted upon by this breast hormone, the anterior pituitary secretes the well attested galactin or prolactin which, carried in turn to the breasts, functionally stimulates milk production. The classic example in man was the pygopus female Blazek twins. One of them became pregnant, during the pregnancy the other twin menstruated till the eighth month, after delivery both twins nursed the child.⁵

3 The relation between suckling and afterpains—our first problem. It is a well-known clinical observation that mechanical stimulation of the nipples frequently causes or intensifies afterpains, i.e., uterine contractions. It is, of course, obvious that this is effected either through the nervous system, a nervous reflex, or through the medium of the circulating blood, a hormonal action. The usual explanation is a nervous reflex. There are two great and (to the writer) insurmountable objections to this idea: (1) the nervous pathways between the breasts and the uterus have never been traced, not even well guessed at, and (2) the time response, usually more than

two minutes, is longer than any known nervous reflex. It is also reasonably certain that all other growth and functions of the breasts are under endocrine control, and it is hard to believe that suckling produces one effect by hormone action and another through the nervous system. Finally, the only known method of stimulating uterine contraction is hormonal. The weight of evidence is for hormonal actions.

The possible hormones concerned in the production of afterpains by nipple stimulation are a postulated "mammin" from breast tissue, or an oxytocin from the pituitary or elsewhere. Mammin is stated to be antagonistic to estrin and postpituitary, but stimulating to the anterior pituitary. There is some evidence that mammary substance or extract has an inhibiting effect or influence on the ovaries and the uterine mucosa and causes the uterine muscle to contract.⁴ There is a considerable literature (predominantly Italian) on the good results obtained with this preparation in uterine bleeding. One writer uses what he terms "automammization" through hot mud stimulation of the breasts in the treatment of this condition.²⁵ In favor of an oxytocin from the pituitary is the fact that suckling stimulates at least one portion of that gland, and also the fact that pituitrin is not only oxytocic but also has a markedly stimulating effect on milk expulsion from the breasts.⁴

To recapitulate—the production or intensification of afterpains by nipple stimulation, e.g., the act of nursing, is hardly a nervous reflex but probably the result of hormonal action. The source of the oxytocic hormone is possibly the breasts, but more likely the pituitary gland. It is, however, well to remember that there are still many large and important hiatuses in our knowledge of the endocrines. We yet do not know what makes the uterus contract, nor do we know that pituitrin or any other oxytocin is the cause of the onset or the continuation of labor.^{24,27}

Cause of Afterpains and Greater Frequency in Multiparae

Rhythmic uterine contractions are normal in all puerperal uteri, after all labors. They serve to empty the uterus, to prevent bleeding, to hasten involution, and to prevent infection. They represent a conservative process which is definitely aided by the good physiologic act of nursing. The older practitioners held that strong afterpains were of good prognostic significance because any serious infection in the uterus stops them, though slight infection seems to make them worse. We come now to our second problem. Why are these uterine contractions, normal after all labors and conservative in purpose, painful at all and why are they usually painful in multiparae and only rarely so in primiparae? The following conventional explanations are quoted from three well known obstetric textbooks.

Williams²⁰ 'In primiparous women the puerperal uterus remains in a state of tonic contraction and retraction, unless it has been subjected to unusual distension, or blood clots or other foreign bodies have been retained in its cavity, as a consequence of which active contractions occur in the effort to expel them. In the multiparous woman, on the other hand, the uterus has lost part of its initial tonicity so that persistent contraction and retraction cannot be maintained and consequently it contracts and retracts at intervals, the contractions giving rise to painful sensations which are known as afterpains.'

Irving¹² 'Afterpains are due to the presence of clots in the uterus and result from the contractions set up to expel them. They are more in multiparae because their uteri are more relaxed and a moderate amount of bleeding is more likely to occur.'

DeLee⁷ 'Multiparae suffer more with painful uterine contractions than do primiparae. Occurring in the latter they give rise to the suspicion of infection or of the retention of clots or placental fragments in the uterus. They are due to lack of tonus of the uterine muscle.'

Let us combine these explanations into a series of statements upon which comment may be made, in agreement or in disagreement, or in calling their accuracy or plausibility into question

Statement 1 Afterpains are caused by contractions of the uterus *Comment* With this there is complete agreement

Statement 2 The primiparous uterus remains postpartum in a state of tonic contraction and retraction *Comment* This is *not* true, for *all* uteri, both primiparous and multiparous, exhibit rhythmic contractions and relaxations after labor. Incidentally, the process of retraction does not continue postpartum for the term implies the presence of something over which or from which to retract

Statement 3 The postpartum multiparous uterus has lost part of its initial tonicity *Comment* There seems to be no question but that *all* uteri lose tone or tonus very rapidly after delivery. Antoine¹ has demonstrated this, and also that the uterus contracts very forcibly after labor, the amplitude of the contractions often being greater than at any other time of its activities. But there is no evidence, experimental or clinical, with which the writer is familiar, that the multiparous uterus postpartum shows greater loss of tone or less tendency to contract than the primiparous uterus, or that its contractions are less strong, or less firm or different in any way

Statement 4 The alleged loss of tone allows more bleeding into the uterine cavity and the uterus is thereby stimulated to contract *Comment* Does any such bleeding occur? Do multiparae have more clots or more bleeding postpartum? Do multiparae with placenta praevia have less afterpains, because in that condition the chief bleeding area is not within the contractile portion of the uterus?

Statement 5 Afterpains are due to the efforts of the uterus to expel blood, clots (particularly incriminated), or other foreign body *Comment* While it is true that most smooth muscle pain with which we are familiar is the result of muscular contraction against resistance, it is also

true that a normal hollow muscular organ, not in the presence of inflammation, expels its contents without pain unless it meets resistance or obstruction. Is the uterus an exception? What and where is the resistance in the birth tract that produces any obstruction? The lower uterine segment and cervix certainly offer no resistance during the usual period of afterpains. On the third day postpartum two fingers can be passed into the uterus. The expulsion of the placenta from the contractile portion of the uterus in the third stage of labor rarely seems as painful as most afterpains. Retained placenta and postabortal and postpartum intrauterine packing rarely cause pain severe enough to require their removal for that reason alone. Afterpains last longer than is necessary for the expulsion of a clot, and they cease gradually and not suddenly, as they would were an obstruction overcome. The frequency of the pains do not show a corresponding number of clots. Why does the blood not simply run out, why must it clot? Is the presence of clots, each time, the cause of the pains that so often follow nursing? Why do not ergot and pituitrin stop afterpains when the alleged clots are expelled, instead of making them worse for some time afterward? It is true, of course, that the expulsion of larger foreign bodies such as placental fragments and larger clots do cause pain though rarely severe, but in this case there is definite resistance due to their size.

The foregoing analysis seems to force the conclusion that the usual explanation of the cause of afterpains and their greater frequency in multiparae is inadequate, is wide open to criticism, and rests on traditional statements and not much scientific evidence.

Two modern viewpoints, the one physiologic and the other anatomic, seem to furnish the clue to a truer or better explanation.

1 The probable cause of pain in any contracting muscle, possibly not even excluding inflammation, is ischaemia of that muscle, whatever the cause of the ischaemia. This is the best explanation

of the pain of skeletal muscles under controlled experimental ischaemia, of intermittent claudication, of coronary thrombosis^{15 17 22} Lackner¹⁴ and Lubin have suggested this possibility in reference to uterine muscle. Mour,¹⁸ in studying dysmenorrhea by intrauterine bag, demonstrated that, when the intrauterine pressure exceeded the systolic blood pressure, the patient felt pain in the uterus. We are not interested in the mechanism or chemistry of this phenomenon,¹⁹ but in the fact that, to the best of today's belief pain occurs in an exercising muscle when it is deprived of blood.

2 There is considerable evidence that the structure of the uterus is profoundly altered by pregnancy.^{4,21} Grossly, multiparous uteri are thicker and harder. Anemia is the basal factor in involution and the blood vessels particularly the arteries, are the center of these changes. According to Goodall⁹ the majority of the uterine arteries are obliterated postpartum, new vessels being later formed in these areas. In and about these areas are deposited large amounts of 'elastoid' material, preceded and followed by various types of degenerative processes. This so-called "pregnancy sclerosis" represents a permanent and characteristic change in the vessels of the uterus, and renders possible the differential diagnosis by the microscope between primiparous and multiparous uteri. It seems reasonable that these extensive changes result in a relatively poor circulation in the multiparous uterus. To this add the fact that all uteri are more or less "blood-tight" directly postpartum. Consequently, uterine contractions of a given intensity, while not able to produce an ischaemia sufficient to cause afterpain in a primiparous uterus, would do so in a multiparous uterus.

To recapitulate Ischaemia of the uterine muscle is the probable cause of afterpains. Their greater incidence in multiparae seems best explained by the fact that the circulation in their uteri has been compromised by involutionary vascular changes in and about the blood vessels,

and a pain producing ischaemia is more easily induced.

Now a few miscellaneous things about afterpains, and finally and briefly their treatment. The greater frequency of afterpains following excessive uterine distension may be due to a more severe immediate damage to the intimate blood supply. The higher incidence of afterpains in the presence of uterine fibroids may be explained on the basis of local ischaemia, in or about the tumors, or because the fibroids stimulate the uterus to stronger contractions. The lag or delay in the appearance of the pains postpartum may be due to the possibility that the uterine circulation at first may be adequate to prevent sufficient ischaemia, or that the oxytocin has not yet been secreted in sufficient quantity. Why do afterpains cease after about forty-eight hours? The high estrin blood content during late pregnancy has sensitized the uterine muscle to oxytocin and it may be that, as the estrin falls, the uterus reacts less strongly to that stimulus.

Some interesting observations were made by several careful and intelligent patients among those studied. They noted that, at times, one or more of the following phenomena accompanied their afterpains, set down here in the order of frequency: (1) Increased vaginal flow—this is a common feature of afterpains which does not at all prove, however, that the expulsion of the blood or clots is directly from the contractile portion of the uterus, or that the increased flow means bleeding into the uterus from which it is expelled by that individual contraction, (2) gas, slight abdominal pain with rumbling and expulsion of flatus, (3) slight frontal headache—it is interesting to speculate if the headache so commonly complained of by puerperal patients might be of pituitary origin, due to increased activity of that gland, (4) nausea (5) desire to urinate, (6) desire to move the bowels. Four of these symptoms—gas, headache, desire to urinate, and desire to move the bowels—may be due to increased secretion of oxytocin. As might be expected, the more

CLINICAL EXPERIENCES WITH SULFANILAMIDE THERAPY

With Special References to Toxic Effects

REUBEN OTTENBERG, M D, New York City

(From the Mount Sinai Hospital)

THERE are two stages in the introduction of a new mode of therapy—the experimental and the clinical. After the fundamental experimental work has been done, each individual group of physicians has to learn from its own practical experience in what clinical conditions the drug is of use, which is the best mode of administration, and what are the accompanying dangers and toxic effects.

I have followed approximately 200 hospitalized cases treated with sulfanilamide. In addition to these a considerable number of cases have been studied and reported to me by colleagues in several of the specialties. From this experience I have been able to draw some definite conclusions. For statistical purposes this experience is of limited value because the number of cases of any one kind is small and because it was impossible, on account of the varied nature of the cases and the necessity for surgical or other forms of treatment, to assemble a series of suitable control cases. I shall present the experience of the group which I represent but my conclusions will be made with due reference to the literature. I have recently reviewed this literature in a paper before the Academy.*

Sulfanilamide was introduced as a specific chemotherapeutic agent for hemolytic streptococcus infections. Further experimental and clinical trials showed that it had a wide, but peculiarly selective, effectiveness. Certain organisms are influenced by it while closely related organisms, for reasons which at present cannot be appreciated, are entirely unaffected.

The diseases in which the drug has been used may be divided into three general groups: (1) those in which it is

definitely indicated, (2) those in which it may sometimes be useful, and (3) those in which it is of doubtful or no use.

CHART I

CASES IN WHICH SULFANILAMIDE IS CERTAINLY USEFUL

Acute Hemolytic Streptococcus Infections
Streptococcus Meningitis
Primary Streptococcus Peritonitis
Erysipelas
Streptococcus Septicemia from any source
Puerperal Infections
Colon Bacillus Infections—particularly of the Urinary Tract
Meningococcus Meningitis and Meningococcemia
Gonococcus Infections
Undulant Fever (Brucellosis)
Chancroid (Ducrey's Bacillus)

The most convincing demonstration of the therapeutic effect of sulfanilamide has been in *hemolytic streptococcus meningitis*. Our experience has been small but conclusive. All 4 of the cases of streptococcus meningitis of otitic origin treated by Dr. Maybaum in the last year have recovered. Also, in a fifth case in which a hemolytic streptococcus meningitis developed as a complication from accidental opening of the meninges in an operation for thoracoplasty, the drug was successful in curing the meningitis. On the other hand, in hemolytic streptococcus meningitis resulting from sinus disease, the results were not favorable. Two cases of this kind were treated and both died. Another case of hemolytic streptococcus infection occurring as a terminal event in a child with hydrocephalus was also unsuccessfully treated.

The difference in the therapeutic results in the cases of meningitis of otitic origin and those of sinus origin is possibly due to the greater ease with which the cases of otitic origin can be adequately drained by the surgeon. In all the meningitis cases sulfanilamide therapy was very intensive and protracted. The drug was given in large doses by mouth and in many of the instances it was also given

*Delivered at a meeting of the New York Academy of Medicine, October 6, 1938

intravenously or subcutaneously. It was not used intraspinally but frequent spinal punctures for the relief of pressure were made. An attempt was made to maintain the concentration of sulfanilamide in the blood and in the spinal fluid well above 10 mg per 100 cc over a long period of time. We are in doubt whether this is necessary but it apparently did no harm.

The results in primary hemolytic streptococcus peritonitis were as good as those in hemolytic streptococcus meningitis. All 4 of the primary cases treated recovered. In 2 of the cases convalescent scarlet fever serum was also administered, but the impression from the prompt recoveries was that the sulfanilamide was the effective agent. It may well be that the combination of the two methods of treatment (a combination to which I refer again in the latter part of this paper) may be advantageous.

On the other hand, in 3 cases in which a hemolytic streptococcus peritonitis was a late complication of some other disease, the results were unfavorable and the patients died. One of these was a case of generalized tuberculosis with amyloidosis. Another was a case of post tonsillitis septicemia occurring in a patient twelve days after a gastrectomy. This patient apparently recovered from the general peritonitis but subsequently died from a residual subphrenic abscess. The third case was one of congenital syphilis in an infant with a complicating hemolytic streptococcus peritonitis. This instance might be regarded as a partial success since the peritoneum became sterilized long before the death by exhaustion of the patient.

In erysipelas our material is too small for conclusions but the clinical impression is extremely favorable. In 14 of the 16 cases there was prompt subsidence of the fever and cessation of the spread of the lesion under sulfanilamide therapy. In 1 of these cases it must be pointed out however, that the patient had done equally well on ultraviolet therapy alone in two previous attacks. Also, none of the cases was extremely grave or had

positive blood cultures. In all of these cases the dosage was moderate the blood level of sulfanilamide was generally brought up to only 2 to 6 mg per 100 cc. It is difficult to assess the value of sulfanilamide in our erysipelas cases because the results in previous years, before the introduction of sulfanilamide, have often been very good. However, the fact that all 16 cases recovered including 3 or 4 very young infants (in whom the high mortality of the disease is universally acknowledged) as well as prompt response to treatment in the majority of these cases, convinced the clinicians that the drug had been effective.

Of the septicemia cases those with sinus thrombosis offered the best opportunity for judging the effect of the drug. It is well known that with suitable surgical intervention the majority of these cases recover. There were 8 cases in the present series and 7 of them recovered. All of them, of course, received surgical treatment. In 2 of them it was the impression that the drug was undoubtedly of great help. The 1 who died was a very complicated case, having had Grave's disease at the time of infection, and was further complicated by suppurative pharyngitis and meningitis.

There were 2 cases of very severe streptococcus septicemia from finger infections. Both of them ultimately recovered, and unmistakably as a result of the drug therapy. One of them a child of five years, also received 120 cc of scarlet fever convalescent serum. Both of them happen to illustrate an important point in the mode of administration of the drug (under which caption I shall refer to them again).

Besides the case of sinus thrombosis the only absolute failure of the drug in hemolytic streptococcus septicemia was in a young woman in whom the blood invasion resulted from an acute tonsillitis. She was intolerant of the drug which was therefore used only in restricted doses (less than 3 grams a day). I shall return to this case later in discussing toxic manifestations of the drug.

A related and most significant case was one of suppurative cervical adenitis complicated by *thrombophlebitis of the jugular vein*. The blood culture showed 500 colonies of hemolytic streptococci per cc. During two weeks the number of circulating organisms diminished progressively under sulfanilamide therapy but the clinical manifestations of sepsis persisted until resection of the internal jugular, subclavian, and innominate veins. After this the patient recovered. This case brings out the very important point (which was illustrated in many other cases) that a persisting focus not freely accessible to the circulation may be unaffected by sulfanilamide in spite of the valuable effect of the sulfanilamide on the general spread of the infection.

Puerperal Sepsis was the earliest and has been one of the most important clinical applications of this new chemotherapy. I have had the opportunity to follow only 1 case. In this instance high fever persisted for fourteen days in spite of sulfanilamide and then dropped suddenly when sulfanilamide administration was stopped. It is difficult to interpret this. The most likely explanation is that the sepsis subsided but that the fever was maintained by the sulfanilamide and this stopped abruptly when the sulfanilamide was stopped. This will be discussed under the heading of toxic effects.

There were 3 cases of *postlaborive sepsis* with positive blood cultures, 1 due to the *B. coli* and 2 due to the anaerobic streptococcus putridus (Veillon). The *B. coli* case recovered gradually. It is difficult to say whether the result was due to sulfanilamide or not. In 1 of the anaerobic streptococcus cases there was a prompt drop in temperature after two days of sulfanilamide therapy. In the other case, as in the postpartum case described already, there was no apparent effect on the temperature during sulfanilamide administration. It rose to $105\frac{1}{2}$ °F the day after the drug was stopped and then dropped to normal in twenty-four hours and remained normal. Again it is difficult to interpret the

result. It is possible that an explanation similar to that offered in the case of postpartum sepsis may be valid.

In *meningococcus meningitis* the results reported in the literature have been extremely favorable. Our own experience consists of only 2 cases. In both of them the results were favorable. In both cases treatment for the first two days was limited to the administration of serum alone with no improvement. Further administration of serum was then stopped and both patients made a good recovery on sulfanilamide. In 1 of the cases the drug was given intraspinally as well as by mouth, but the intraspinal injections caused shock and were abandoned.

In *undulant fever* the results in the literature are increasingly favorable. Our material consists of only 1 case. In this case sulfanilamide was given approximately in the ninth week of the disease. A positive blood culture had been reported in the third week of the illness. The drug was given rather intensively, 330 grains in three days. The patient thereupon developed dizziness, disorientation, and an eruption on the face and neck. The administration of the drug was stopped. The temperature gradually came down to normal during and after the administration of the drug. While it is probable that sulfanilamide did exert a therapeutic (as well as a toxic) effect in this case, this is not certain since spontaneous improvement sometimes occurs about this stage of the disease.

The use of sulfanilamide in the treatment of *gonococcus infections* is very important. Dr. Lewis Mann has analyzed the results in 47 cases of gonococcus infection in the male treated in the outpatient department. Of the total cases there were 29 cures, 16 failures, an average of 60 per cent cures. The cures were obtained in chronic as well as acute cases. The average duration of treatment was twenty-eight days which is somewhat shorter than with previous methods of treatment. In all cases the drug was continued at least a week after the disappearance of the gonococci. The dosage

was small, usually 2 grams a day, and there were no serious reactions observed. In 12 additional cases sulfanilamide was tried as an irrigation solution exclusively without internal administration. Used in this way it was absolutely valueless. As the result of the failure of sulfanilamide treatment in 40 per cent of the cases, subsequent cases have been treated with a combination of the usual local treatment and sulfanilamide by mouth, since it is impossible to determine whether a given case will be influenced by sulfanilamide or not. This experience confirms that reported in the literature, except that the period of treatment in our clinic does not seem to have been shortened as much as in the case of other workers.

There were 2 cases of severe *gonococcal polyarthritis*. In neither of them was there a striking therapeutic effect. One patient (who also received a hyperthermia treatment while receiving sulfanilamide) was 1 of the cases (see below) which developed intense jaundice and a moderate grade of acute hemolytic anemia. It is possible that the addition of the hyperthermia may have precipitated the blood destruction.*

Chancroid—Although I have not had the opportunity personally to follow any cases of chancroid under sulfanilamide therapy, Dr Kornblith,³ who was the first to treat these cases with this drug, has given me the privilege of mentioning his series of 50 completely diagnosed cases with 100 per cent cures. Forty-nine of the 50 cases were cured within two weeks and the other case was cured within three weeks. The effect on the Ducey bacillus is remarkable and specific. These cases with our best previous treatment usually dragged on from three months to several years.

Miscellaneous Urinary Infections—Since Helmholtz³ showed it to be effective against the colon bacillus, bacillus mucosus capsulatus, and the proteus bacillus, the use of sulfanilamide in the treatment of urinary infections has become ex-

tremely important. In urinary infections the drug has been given in moderate doses, most commonly 30 grains (2 grams), occasionally 45 grams (3 grams), a day. This results in a sufficiently high concentration in the urine (60 to 100 mg per 100 cc). Dr Lewis Mann has been kind enough to analyze 40 cases of renal, bladder, and prostatic infections for me. The use of the drug locally as an irrigant is ineffective. It obviously works primarily on the organisms in the tissues, although it may have a sterilizing effect on the urine.

CHART II

URINARY TRACT INFECTIONS ACCORDING TO ORGANISM⁴

| | CASES | CURED |
|-------------------------------------|-------|-------|
| B. Coll | 20 | 22 |
| B. Proteus | 12 | 3 |
| B. Friedländer | 2 | 0 |
| B. Pyocyaneus | 2 | 1 |
| Staphylococcus Aureus | 2 | 1 |
| Nonhemolytic Streptococcus | 2 | 2 |
| Bacterococcus combined with B. Coll | 3 | 1 |
| | 52 | 29 |

The strikingly good results in the cases infected only with the colon bacillus confirm the experience of all who have written on the subject. The failure to cure most of the cases of *B. proteus* infection is contrary to the results reported in the literature and is hard to explain. Possibly more intensive dosage should be used in these cases. The results with all the other organisms are of little significance because of the small number of cases. Surgical measures used along with sulfanilamide may well have been responsible for cures in some of the instances.

The best results were obtained in cases of cystitis of which there were 33, 20 of these were cured. The results in prostatitis were also good, 7 cases with 5 cures. The results in renal infections were less encouraging, 9 cases with only 3 cured. In the presence of renal calculi there were no successes. Dr Mann was able to follow up many of the cases for long periods up to a year and found that in general if the mechanical conditions were satisfactory the cures were permanent. Four cases of cystitis and pro-

* The combination of sulfanilamide and hyperthermia therapy has been recommended in gonorrhea by Balenger, Elder and McDonald.⁴

statitis were outstanding, all being infected with the colon bacillus and 1 of them having an enterococcus in addition. They were of 13 years, 8 years, 6 years, and 4 years standing and had been unsuccessfully treated with every conceivable form of therapy. They were treated with sulfanilamide and prostatic massage in 1937. The cures were prompt and when the patients were examined in 1938 the cures were found to be permanent. In general our urologists believe that the introduction of sulfanilamide has given them a higher percentage of cures in urinary infections than any previous form of drug therapy.

CHART III

CASES IN WHICH CLINICAL RESULTS ARE LESS CERTAIN
BUT IN WHICH THE DRUG MAY BE OF VALUE

| | |
|--|------------------|
| Acute Streptococcus Infections | |
| Tonsillitis | Bronchopneumonia |
| Otitis | Empyema |
| Mastoiditis | Cellulitis |
| Sinusitis | Adenitis |
| Scarlet Fever | Cholecystitis |
| Pneumococcus Infections | |
| Urinary Infections with B. Proteus, B. Typhosus | |
| Staphylococcus Aureus and possibly other organisms | |
| Gas Bacillus Gangrene | |
| Ludwig's Angina | |
| Non-specific Colitis | |
| Malaria | |
| Trachoma | |

Should one use sulfanilamide in every case of hemolytic streptococcus infection whether mild or severe? The question is an important and difficult one and the answer depends to a large extent on a consideration of the possible untoward effects of the drug. This I shall discuss in detail before the end of this paper. On account of these effects there is doubt regarding its use in the milder cases of streptococcus infection, this is a question for further clinical study before we can accurately demarcate where the line is to be drawn. This applies to such conditions as tonsillitis, otitis, and mastoiditis.

On the subject of *simple otitis* and *acute tonsillitis*, I cannot present any evidence because all the cases treated in the hospital were complicated by more serious diseases. Of 11 such cases of tonsillitis there were only 2 in which the clinicians felt that the result on the tonsillitis was prompt and striking. It is

very important that someone in a position to collect information accurately should make an intensive study of the results in tonsillitis and otitis, because the drug is being prescribed (often without bacteriologic control) in an enormous number of such cases in private practice.

Cases have been reported elsewhere in which *mastoiditis* subsided⁵ with no other treatment than the administration of sulfanilamide, and trial of the drug would seem fully warranted in any case not showing urgent indications for operation. It is difficult to evaluate the results in our cases of mastoiditis because all of them were admitted to the hospital for the purpose of being operated upon. Of the 8 cases in which the drug was used there were only 3 in which the clinical impression was that the use of sulfanilamide had a decided influence in hastening recovery. One of these was a case complicated by an extra-dural abscess. Sulfanilamide may well have had a beneficial result in all the other cases but it is impossible from the nature of the clinical evidence to say so with certainty.

An important group of cases are those with *streptococcus bronchopneumonia* and particularly cases complicated by *streptococcus empyema*. There was 1 case of very severe and protracted bilateral streptococcus bronchopneumonia in an adult with recovery on sulfanilamide treatment. There were 8 cases of infected pleural effusions in which streptococci and a smaller or larger number of pus cells were found in the pleural effusion. Of these 3 recovered under sulfanilamide treatment, without operation. The other 5 cases either had such large effusions or were so toxic that it was not considered safe to avoid operation. Of these, 2 were extremely sick and the impression gained was that in these 2 cases the detoxifying effect of the sulfanilamide played an essential role in the recovery, even though operation was subsequently done. In one such case the empyema became sterile before operation was done. In the other 3 sulfanilamide may or may not have been of use.

There were also 2 cases of empyema complicating *putrid lung abscesses* in both of which in addition to anaerobes, hemolytic streptococcus was demonstrated. In both of them the impression was that the administration of sulfanilamide did have a salutary effect on the temperature curve.

Miscellaneous forms of cellulitis due to hemolytic streptococcus were treated by sulfanilamide in many instances. They were all subjected to the usual surgical therapy and in most of them it was impossible to draw definite conclusions as to the effect of the drug.

Sulfanilamide was used in only a few cases of *pneumonia*, because the clinicians were unwilling to give up serum in the types for which serum was available. It was used without serum in 3 cases of Type III pneumonia. Of these, 2 recovered, but it is difficult from the study of the temperature curves to decide whether sulfanilamide played a role in the recovery or not. In an additional case of Type III pneumonia the drug was administered simultaneously with Type III antipneumococcus rabbit serum and the patient recovered. This was a desperate case and it is difficult to decide which of the two methods of treatment was responsible for the rather rapid defervescence. Sulfanilamide was also tried in 3 other cases of miscellaneous types of pneumonia, IV, VII, and XI. Two of them died, 1 of them after the development of empyema. Our very small experience hardly justifies us in expressing any opinion of the use of sulfanilamide in pneumococcus infections.

Pylephlebitis—We have used sulfanilamide therapy in 3 cases of *suppurative phlebitis of the portal vein*. Two of these cases recovered.⁶ A case with blood culture showing the Friedlander bacillus was fatal. Of the 2 cases which recovered 1 was proved by exploratory operation to be a typical case in which the infecting organism was the colon bacillus. The other case developed characteristic symptoms following an operation for infected hemorrhoids but as

the patient recovered the diagnosis was never confirmed by operation.

In *nonspecific colitis* trial with sulfanilamide is not illogical since the colon bacillus undoubtedly plays a role in the toxicity of many cases, even though the nonhemolytic streptococcus according to Barger may also be an important factor. Dr. Winkelstein who is studying these cases reports that 5 cases thoroughly treated with sulfanilamide showed no decided results. 2 of them showed transient subjective improvement. Since the introduction of soluble prontosil in tablet form for oral use under the name of neoprontosil, 4 cases have been treated following the dosage recommended at the Mayo Clinic.⁷ It is too soon to speak of results but 1 case has shown remarkable improvement and 1 case, encouraging improvement.

CHART IV

CASES IN WHICH SULFANILAMIDE IS OF DOUBTFUL OR NO VALUE

Most forms of Infectious Arthritis
Rheumatic Fever
Staphylococcus General Infections
Influenza Bacillus Meningitis
Friedlander Bacillus Infections
Putrid Lung Abscess
Urinary Infections with Streptococcus Fecalis
Subacute Bacterial Endocarditis

On account of the adverse reports appearing in the literature there were very few trials with sulfanilamide in arthritis. I have records of only 1 case of *nonspecific infectious arthritis* and 1 of *rheumatic fever* treated with it. In neither case was there evidence of any therapeutic effect.

In 4 cases of *subacute bacterial endocarditis* the drug received a thorough trial with no effect on the temperature curve or the number of bacteria in the blood.

Sulfanilamide therapy was tried in 4 cases of *meningitis due to the influenza bacillus*. Two of the cases were treated in addition with anti-influenza serum intrathecally. All 4 cases died and there was no decisive influence on the course of the disease.

On account of the recovery of 1 case of influenza meningitis reported by Neal and Applebaum,⁸ with a combination of

serum and sulfanilamide we believe that this combination should receive further trial. The drug was also tried in 1 case of *tuberculous meningitis* with a negative result.

Staphylococcus Aureus Infections—From the experimental work and the literature it is probable that sulfanilamide has little effect on *staphylococcus aureus* infections. On the 10 cases in which it was tried, 5 were local infections, carbuncles or cellulitis, and though all of these ultimately recovered it is uncertain, from the clinical course, whether the drug played any part. A sixth case was undoubtedly a septicemia following an axillary lymphadenitis, although no positive blood culture was obtained. The patient gradually recovered and we are likewise unable to express a definite opinion as to whether the drug played a role. In 2 of the cases of *staphylococcus aureus* septicemia following osteomyelitis the drug had no influence and the patients died. In a third case of *staphylococcus osteomyelitis* but without blood invasion there was a rather rapid drop in temperature and the drug may have had some effect.

In a case of *staphylococcus aureus* septicemia with cortical kidney abscesses and multiple lung abscesses all consequent on furuncles of the leg, the patient, previously regarded as hopeless, began to improve as soon as sulfanilamide administration was begun and made a complete recovery without operation. In evaluating this we must remember that such cases occasionally (though rarely) recover spontaneously.

In 1 case of apparent *thrombosis of the cavernous sinus* consequent on a furuncle of the nose showing a positive blood culture with *staphylococcus aureus* the patient made an astonishing recovery. This patient also received *staphylococcus* antitoxin. This is a disease from which recovery is extraordinarily rare.* In spite of the failure of sulfanilamide generally in *staphylococcus* infections

the possibility must be held in mind that the drug may have a greater effect in human beings than in experimental animals. I believe it is worthy of a further trial.

Ludwig Angina—On account of recent reports of brilliant success in 2 cases of Ludwig's angina¹⁰ in which the hemolytic streptococcus was the infecting organism, it is worth mentioning our 1 case of this disease in which the drug was used. The patient died. The majority of cases are due to anaerobes but a hemolytic streptococcus is sometimes also present and the drug seems worthy of trial in these desperate cases.

Toxic Effects

CHART V

I Common and Not Very Serious

- 1 Anorexia, nausea, vomiting, sense of oppression
- 2 Dizziness, somnolence, slight mental confusion
- 3 Acidosis, hyperpnea
- 4 Secondary fever
- 5 Secondary anemia
- 6 Moderate leukopenia
- 7 Scarlatiniform or morbilliform rashes (5 cases)

II Rare but at Times Dangerous

- 1 Disorientation or actual psychosis (4 cases)
- 2 Toxic encephalopathy—1 case (died)
- 3 Diplopia—1 case (transient)
- 4 Severe dermatosis—1 case (died)
- 5 Albuminuria (1 case)
- 6 Acute hemolytic anemia with hemoglobinuria, renal insufficiency, and jaundice (2 cases)
- 7 Hemolytic anemia with severe jaundice (toxic hepatitis) (4 cases)
- 8 Agranulocytosis (2 cases—1 died)

It is difficult to estimate the real degree of danger associated with the drug. The difficulty is that it has almost no ordinary toxicity in the sense of symptoms which can be relied on to appear with progressively increasing doses in human beings. Its toxic results in clinical practice are almost all in the nature of idiosyncrasies. People who tolerate a moderate dose usually can stand enormous dosage without further symptoms. On the other hand the few really serious toxic results come on often with lightning-like suddenness in persons who have had relatively small doses. This gives the physician a certain feeling of anxiety in instituting the administration of the drug and is a reason for the careful consideration of the indications in the relatively less dangerous types of disease.

Cyanosis.—The cyanosis which so often occurs is to be regarded as a normal ac-

* MacNeal and Cavallo have reported a similar recovery with sulfanilamide in a case due to the hemolytic streptococcus.⁹

companionment of sulfanilamide therapy rather than as toxic manifestation. It occurs in all the cases which receive large doses and in many of those which receive small doses. It is harmless, is not accompanied by anoxemia, diminished oxygen carrying power of the blood, or dyspnea.^{11,12} It is probably not altogether due to the methemoglobin which frequently is found in small amounts, but is caused in part by a staining of the red blood cells with a blue oxidation product of the drug formed spontaneously in the body. This substance can be demonstrated experimentally *in vitro* if a dilute solution (1-10,000) of sulfanilamide is exposed for one minute to ultraviolet light.¹³

Certain *subjective symptoms* which are not very rare are nausea, loss of appetite, occasional vomiting. These seldom interfere with the administration of the drug which can always be given parenterally if necessary. The same may be said of dizziness and slight mental confusion which a few patients complain of. This whole group of symptoms are seldom the precursors of more serious toxic symptoms.

In a few patients, however, the confusion goes on to a more serious mental state with disorientation, mania, or other signs of a toxic *psychosis*. We have had 4 such cases, 1 of them fatal. This was a man of 51, with bilateral pyelonephritis, in whom progressive toxic encephalopathy appeared two weeks after the sulfanilamide had been discontinued, it is possible that the death may have been due to cerebral softening from some other cause. There was unfortunately no post mortem examination. In the other cases the psychotic symptoms appeared during the administration of the drug and cleared up promptly when the drug was discontinued.

A *generalized skin eruption*, usually morbilliform or somewhat scarlatinian in character (in one case accompanied by vesicles and in another by bullae) occurred in 6 of our cases. In most instances it appeared after the drug had been given for a considerable time in

fairly large doses. In the majority of cases it was accompanied by a recrudescence of fever and disappeared in a few days when the drug was stopped. Usually the eruption does not need to be regarded as a serious complication of the disease.

The only instance in which the skin eruption was of grave significance was the case of streptococcus septicemia from tonsillitis already referred to. This young woman was very intolerant to the drug. She vomited after the first 35 grains ($2\frac{1}{2}$ grams) and the drug was stopped. A week later she developed a measles like eruption. Because the septicemia was getting worse the drug was resumed, only 40 grains ($2\frac{2}{3}$ grams) a day being given for four days. The eruption developed great intensity and acquired a bullous character and extensive lesions appeared in the mouth and throat. The patient died three days after the drug had been stopped. While the death was primarily due to streptococcus septicemia, the drug contributed an important toxic factor.

Because of the bullous character of the skin eruption in this case I was uncertain at the time if the eruption was due to sulfanilamide. But recently Dr B Kornblith has told me of a case of gonorrhea which under treatment with neoprontosil tablets developed an extensive rash resembling erythema multiforme and showing numerous bullae.

Secondary Fever—Another of the less grave toxic effects is the secondary fever due to the drug. There were a few such cases, it is difficult to say how many because the diagnosis was so often in doubt. In all of them the drug had been given a considerable time, one or more weeks, and the evidences of the original febrile infection were usually subsiding or had completely subsided, when a secondary rise of temperature occurred. In the cases which developed extensive skin eruptions, secondary fever was the rule. In nearly all instances the fever disappeared promptly when the drug was stopped. The chief importance of the fever lies in the difficulty in determining

whether the fever is due to the drug or to a recrudescence of the original infection.

Another relatively minor complication of which I have no personal experience is *acidosis*. There were no pronounced cases of it on the adult services but Dr Jerome Kohn tells me that on the pediatric service many of the younger children receiving sulfanilamide showed mild grades of acidosis. The low CO_2 combining power of the blood was formerly attributed to acidosis, but according to the more recent work of Hartman¹⁴ it may be due to an actual alkalosis the result of hyperpnea which has to be regarded as a direct effect of the drug.

The two really dangerous complications of the drug are blood injuries, the *acute hemolytic anemia* and the *agranulocytosis*. The acute hemolytic anemia cases grade gradually into the jaundice cases which are apparently a milder form of the same hemolytic process.

I have seen 2 cases of acute hemolytic anemia of the severe type. The 2 cases showed an extraordinary resemblance to each other. Both were young men in whom the drug was taken for ordinary sore throats. In both the dosage was very small. In 1 case the total amount of drug given was between 2 and 4 grams, in the other the total amount was 2.3 grams of sulfanilamide by mouth and 4 cc of prontosil intramuscularly. In both cases there was a free interval of well-being with normal temperature lasting two days before the onset of severe toxic symptoms. Then with great suddenness began hyperacute diarrhea, vomiting of coffee colored fluid, hemoglobinuria, increasing jaundice, and rapidly progressing anemia. The blood hemoglobin in both cases fell to 32 per cent in spite of one transfusion in the one and four transfusions in the other case. There was a striking increase in leukocytes and in blood platelets (41,000 white blood cells and 1,100,000 platelets in one case) as well as marked outpouring of reticulocytes and nucleated red blood cells. The amount of urine decreased progressively in both cases and 1 patient had a complete anuria for twenty-four hours.

There was a marked nitrogen retention in both cases and the urine contained large amounts of albumin, red blood cells, and granular casts. Both patients were very desperately sick, in fact nearly died, but both did ultimately recover.

Of 4 cases of *jaundice*, the first occurred in a woman with a primary streptococcus peritonitis, the jaundice was relatively mild, was not accompanied by a severe anemia, and disappeared when the drug was stopped. The second was more severe, the hemoglobin dropped to 38 per cent, numerous nucleated red blood cells were seen in the blood smears, and transfusion was needed. In this case the original disease was saphenous thrombophlebitis and inguinal adenitis and the total dose taken was only 9 grams in five days.

The third and fourth cases were still more serious, they showed marked anemia but no hemoglobinuria. Both of them had repeated vomiting and were extremely toxic. The dosages of the drug which produced these cases were not very large.

In the third case, a man of 45 with gonococcus arthritis, the jaundice developed after a total dosage of 56 grams in two weeks. It appeared immediately after a hyperthermia treatment. The patient's hemoglobin dropped to 45 per cent and he developed profound jaundice with blood bilirubin of 3.8 mg, a normal total blood cholesterol of 225 mg, but cholesterol esters of only 37 mg per 100 cc. On blood transfusion and intravenous glucose he recovered.

The fourth patient, a man of 35, with a recurrence of a chronic prostatitis and pyelonephritis developed a very severe jaundice after receiving either $6\frac{1}{2}$ or 9 grams of sulfanilamide. (The uncertainty is due to ignorance as to whether he took 5- or $7\frac{1}{2}$ -gram tablets.) The toxic symptoms were so profound that for a while it was feared that he was developing an acute yellow atrophy of the liver. The icterus index reached 200. For a number of days the stools were acholic. There were heavy traces of albumin in the urine and 15 to 20 granular casts per high

power field. The total blood cholesterol dropped to 111 mg and the hemoglobin to 55 per cent.

This patient was a chronic alcoholic and had had a mild attack of jaundice four years before. Although apparently well he is still (2 1/2 months after the acute attack) slightly jaundiced with an icterus index of 15 and is probably developing toxic cirrhosis of the liver.

In none of these anemia or jaundice cases was there any depressing effect on the leukocyte picture. On transfusion, liberal venous infusion, and high carbohydrate diet all of the patients finally recovered.

Leukopenia and Agranulocytosis—There were a number of cases of moderate grades of leukopenia (4,000-5,000 or 6,000 white blood cells) with no striking changes in the differential blood count. In all of these instances the drug was promptly stopped and it was never certain whether the leukopenia was due to the drug itself.

There were 2 cases of true agranulocytosis. The 1 was a very severe case of otitic sepsis complicated by sinus thrombosis and metastatic osteomyelitis. He developed an extreme grade of agranulocytosis after having received enormous amounts of the drug. The drug was stopped and with numerous transfusions he gradually overcame the agranulocytosis and after a long and complicated course is now slowly recovering.

The other case of agranulocytosis developed in a man of 22 who had a bilateral bronchopneumonia due to pneumococcus Type VII, complicated by an acute pericarditis. Because of the isolation of a hemolytic streptococcus from the sputum (on admission and before identification of the pneumococcus) he was given 6 grams of sulfanilamide during the first day. When the pneumococcus was found the sulfanilamide was stopped and serum was given. It was two weeks after the administration of the sulfanilamide that the agranulocytosis appeared. It came on suddenly, there having been a normal blood count five days before. The patient died two days later in spite of blood transfusions and other therapy. On ac-

count of the two weeks' interval between the rather small doses of sulfanilamide and the appearance of agranulocytosis in this case it is not absolutely certain that the agranulocytosis was due to the drug. However, the clinical picture of agranulocytosis is always the result of degeneration of the bone marrow, when it occurs after other poisons such as benzol, salvarsan, or amidopyrine,* there usually is a free interval which in some cases is of many weeks duration*.

Albuminuria—Because kidney damage is not mentioned in the literature as one of the toxic manifestations of sulfanilamide, I wish to record 1 case of marked albuminuria. It occurred in a young woman with a very severe recurrent uveitis. This was a case (as so often) of unknown etiology in which all possible foci of infection had been looked for without success. There was a normal urine examination immediately before sulfanilamide therapy was started. After one week of sulfanilamide treatment there was a very marked (four plus) albuminuria. Unfortunately the patient had been treated at the same time with intramuscular injections of boiled milk and it was impossible to be certain whether the albuminuria was due to the milk injections or to the sulfanilamide. Both forms of treatment were continued for a week longer and as the albuminuria persisted the sulfanilamide was then stopped. The milk injections were continued for another month. At this time the albumin in the urine was found to be only a trace. There was then a flare-up of the uveitis and the patient was put on sulfanilamide again (3 grams a day as previously). After four days of sulfanilamide the urine again showed three plus albumin and this time also showed a few red blood cells (1 to 3 per high power field in a centrifuged specimen). The sulfanilamide was again stopped and four days later the albumin had again dropped to a trace, although a few red blood cells were still present. When seen a month

* Since writing the above I have seen another fatal case of agranulocytosis. It occurred after one week of sulfanilamide therapy for gonorrhea of the cervix uteri.

later she still had a faint trace of albumin but no formed elements. At no time were casts seen, nor did the patient ever have an elevation of blood pressure or any other clinical manifestation of nephritis. With regard to the eye condition the patient was subjectively convinced that she had improved more rapidly than in her previous attacks, although the ophthalmologist who watched her was unconvinced of any unusual objective improvement.

Reviewing all the toxic effects there were three instances in which toxic manifestations may possibly have contributed to death: the case of skin eruption complicating tonsillar septicemia, the case of agranulocytosis complicating pneumonia, and the case of toxic encephalopathy complicating calculus pyelonephritis. There were 4 cases in which toxic blood destruction beyond a doubt nearly killed the patients. These were the 2 cases of acute hemolytic anemia complicating tonsillitis, the case of jaundice (subacute yellow atrophy of the liver in all likelihood) complicating pyelonephritis, and the case of agranulocytosis with sinus thrombosis. It may or may not be significant that 3 of these 7 most severe toxic cases occurred in instances of tonsillitis.

It is possible that my experience represents a somewhat one-sided picture of the frequency of toxic manifestations since (because I was known to be interested in the drug) I was usually asked to see the toxic cases, while a large number of cases under treatment which ran a normal course failed to come under my observation.

It is evident, however, that we are dealing with a treacherous drug—one which has enormous therapeutic value and therefore cannot be abandoned, but which nevertheless, on rare occasions, due to idiosyncrasies which have as yet no explanation, may develop the most destructive effects. In this regard sulfanilamide is in the same class as salvarsan and cinchophen. I feel, therefore, that in spite of the rapid and brilliant cures which can usually be effected, the physician should not be tempted to give the

drug for minor infections such as ordinary tonsillitis, otitis, and well-localized cellulitis. The need for watchfulness during administration of the drug is obvious. Ambulant patients should receive it only if they can be observed frequently.

Mode of Administration—In all cases where oral administration is possible it is the method of choice. In adults the tablet form is most convenient and in children the powdered drug can be administered in orange juice. When oral administration is not possible or when it is desired to give a very large dose within the first twenty-four hours, subcutaneous or intravenous administration of 0.8 per cent sulfanilamide or of prontosil can be substituted. Except in such emergencies intravenous use of the drug is to be avoided because it leads to rapid excretion and does not lend itself so readily to the maintenance of a high blood concentration of the drug set up as an objective of therapy by Marshall¹⁵ and by Long and Bliss¹⁶. On the pediatric service on account of the greater tendency of infants or young children to acidosis the sulfanilamide when given by injection has been dissolved in Ringer's solution made alkaline by adding 0.6 per cent of sodium lactate. Fluids are administered freely to the patients except in the urinary infections when the amount of fluid is limited moderately in order to favor a high concentration of the drug in the urine.

Dosage—There is as yet no universally accepted standard dosage. We have generally adhered to that worked out by Colebrook and by Long and Bliss. The pediatric service, however, has usually given a proportionately larger dose, namely, 0.2 gram per kilo. This is almost 2 grams for every 20 pounds body weight, or about twice the usual dose for adults. Since we have had Marshall's method of determining the concentration of the drug in the blood and urine we have made the effort in the severer cases to keep the blood concentration up to about 10 mg per 100 cc of blood (1-10,000). In most of the milder cases we have been satisfied with a concentration of 3 to 6 mg per 100 cc.

In cases with any impairment of kidney function, moderation in dosage and the frequent use of the Marshall method to check up on the blood concentration of the drug are essential.

On the ear service the dosage has been very intensive and particularly in the meningitis cases the blood concentrations were kept to at least 15 mg. or more per 100 cc. It is not yet certain whether this is necessary, good results have been reported elsewhere from much smaller dosage. The only case in which it may have done harm was one of the cases of agranulocytosis already referred to.

On the genitourinary service the dosage has generally been much smaller than on the other services, usually a maximum of 3 grams a day for adults. This has generally produced sufficient concentration in the urine (75 to 100 mg. per 100 cc.) In all the departments the usual procedure has been followed of dividing the total daily dose into 4, 5, or 6 parts and giving it at uniform intervals during the twenty four hours so as to keep the concentration of the drug in the body as nearly as possible at a constant level. In all very severe cases such as meningitis and septicemia the effort has been made to bring the blood concentration up to the desired level in the first twenty four hours. This generally required either double dosage by mouth or the administration of the drug both by mouth and by vein.

During subsiding periods of infection the dosage is, as a rule, gradually cut down. It is always advisable to continue the drug for a variable period, at least for some days after the temperature has reached normal and the infection has subsided. This is particularly important in very menacing types of infection such as streptococcus meningitis in which the survival of only a few micro-organisms in the tissues might have a disastrous result.

There were very many instances in our experience in which the administration of the drug was stopped too soon and in which the disease recurred after an interval of a few days. In one such ex-

ample, a case of septicemia from a finger infection, it recurred twice and after the third plateau of fever sulfanilamide was continued for a month in order to make certain that there would be no recurrence.

Prolonged ingestion of sulfanilamide seems to be harmless. Some of our patients took it for months. Toxicity, if it occurs, usually occurs early.

Other methods of treatment should not be neglected because reliance is placed on sulfanilamide. There is experimental evidence that sulfanilamide and immune sera have a mutually intensifying (what Mellon¹⁰ calls a potentiating) effect. In many of our most severe cases, scarlet fever convalescent serum (undoubtedly the most effective and widely valent serum for hemolytic streptococci) was used. For grave infections with meningococcus, pneumococcus, gas bacillus, influenza bacillus, or staphylococcus aureus the simultaneous use of sera seems wise.

In many of the cases supportive treatment with blood transfusion was used freely and was of the greatest value.

Precise bacteriologic diagnosis should be made in every case, but in a serious illness treatment often has to be started without waiting for the laboratory report. When the cultures show mixed infections and one of the germs is known to be susceptible to the drug (as in empyema due to anaerobes and hemolytic streptococcus, urinary infections due to colon bacillus and enterococcus) the results are often very good. Possibly in these cases the drug helps to suppress a symbiosis. In the sore throats of children accurate and rapid bacteriology is especially important. Many of these cases are due to the staphylococcus aureus and do not respond to sulfanilamide.

In occasional cases in which a bacteriologic diagnosis is not possible it may be justifiable to try sulfanilamide. We had one such case of very high fever (104 F. to 105 F. daily) lasting for 2½ months and defying every possible method of diagnosis. When the patient was almost moribund he was cured in a few days by sulfanilamide.

It is important in using sulfanilamide not to relax vigilance when the patient is doing well. It has happened to us repeatedly that while the temperature was coming down, or even after it had been normal for some time and all toxic symptoms had subsided, insidious localizations of pus or metastatic foci appeared.

Sulfanilamide seems to be most effective against micro-organisms which are rapidly spreading, are more or less free in the tissues, or are in the general circulation. It undoubtedly reaches closed cavities, such as nasal accessory sinuses and walled-off abscesses, but perhaps in lesser concentration. In these cases more prolonged treatment and, in most instances, surgical intervention, are necessary.

1939 ANNUAL MEETING, ANNOUNCEMENT OF AN INNOVATION

At the forthcoming Annual Meeting of the Medical Society of the State of New York, the newly formed Section on Gastroenterology and Proctology will hold its first session and for its first day has decided to conduct a type of meeting new to our Society, but which has proved of interest in other similar organizations in the past few years.

The morning will be devoted to a Round Table discussion of subjects to be submitted in advance by any member of the State Society who expects to attend the meeting. A

round table group of speakers, consisting of two gastroenterologists, an internist, a surgeon, and a roentgenologist will discuss the previously submitted subjects in turn, supplemented by brief discussions from the floor. This type of meeting should provide an interesting innovation.

It will be much appreciated by the officers if members of the Society will send in questions for discussion either to the Chairman, Dr A F R. Andresen, 88 Sixth Avenue, Brooklyn, or to the Secretary, Dr John L Kantor, 145 West 86th Street, New York City.

HEALTH INSURANCE FAVORED BY MILLIONS

Millions of Americans are interested in voluntary health insurance—according to a nationwide cross-section survey by the American Institute of Public Opinion, of which George Gallup is director.

The Institute's study, which comes after months of debate on the merits of health insurance by physicians, medical economists, and government officials, indicates that approximately 25,000,000 persons would be interested in paying as much as \$3 a month for complete medical and hospital protection, as reported in the *New York Times*.

This is a figure that many economists believe would be "the top" for guaranteed medical care

Some existing insurance plans are providing such care for as little as \$2 a month.

If the cost were limited to this latter figure, the Institute survey indicates that approximately 32,000,000 persons would take advantage of it.

The survey indicates that the bulk of the potential customers for medical and hospital insurance comes from the upper and middle economic groups. They come, in other words, from those earning at least \$20 a week.

But a large group of Americans earning less than \$20 a week say the cost would still be too high, they could afford to pay only \$2 to \$3 a month, "if the whole family can be included for that."

GENERAL PARESIS

Biologic and Serologic Variants Affecting the Results of Treatment

BENJAMIN POLLACK, M D, Rochester

(Senior Assistant Physician State of New York Department of Mental Hygiene Rochester State Hospital)

IN CONSIDERING the results of any form of treatment, usually the organic and objective signs are considered rather than a survey of the entire individual—the product of his heredity and environment. There are individuals who are born of sound stock whom no acquired condition extrinsic or intrinsic, can apparently render psychotic. However, there are others whose mental equilibrium may be disturbed by any one of many conditions without apparent cause except the physiologic processes associated with puberty and adolescence, reproduction, and the menopause. It is now well recognized that fairly definite abnormalities of biologic psychodynamics can be discovered in a majority of cases. Between the two extremes of normal behavior and psychotic behavior may be found all gradations of mentality.

Every case of mental disease must be regarded as a biologic problem so that the study resolves itself into the accumulation of a knowledge of what the individual is born with—nature, and what has happened after birth—nurture. The former can be approximately probed only by a study of the individual's ancestry especially, together with a study of the immediate family history in both the direct and collateral lines by which many important facts relating to the transmission of a psychopathic taint may be discovered. It must also be borne in mind that this psychopathic tendency may be expressed in various types of manifestations such as neurosis, chorea, epilepsy, migraine, hypochondriasis, or it may be demonstrated by temperamental eccentricities such as undue optimism, depression, or by an "inborn" lack of moral sense or feeble will power. It may also be revealed by the frequency of crime, suicide,

or drunkenness in members of the same stock. It is not at all unusual to find both genius and psychopathic tainting in members of the same ancestry.

Inherited tendencies, of course, may be modified by proper nurture associated with a good environment with adequate suggestion and imitation, or they may be allowed greater play by exposure to poor companionship, unemployment, or temptations such as drink. It is exceedingly difficult to estimate the exact part which heredity plays in the production of the fixed psychotic types as we see them. There is, however, no doubt that certain types of mental disease may be transmitted with greater frequency than others such as manic depressive psychosis.¹ However, it would appear that the general rule is for the different types to appear in different generations.

It is, however, evident that nature, by intensifying the disease, crystallizes the unsound portions of the stock into one of the offspring. The latter, becoming psychotic, is frequently unable to propagate his stock. It seems that in this way nature tends to end or mend the degenerate stock although it is recognized that the psychopathic tendency may be revised in strains undergoing purification. Morel has held that in irritable cases, weakness, such as neurasthenia, may serve as a starting point for the degeneracy of the stock. Added to this unstable mechanism are other factors, i. e., alcoholic abuse, sexual excesses, ungratified sexual instincts, stress of city life, religious fervor, competitive examinations, the imposition of celibacy on large numbers of men and women, and the physiologic conditions of sexual life whereby the maternal or paternal instincts are starved. Again, all forms of

emotional stress, psychic as well as physical trauma, and depressive after-effects of various infectious diseases, may result in an exacerbation of a latent or dormant psychopathic taint in the previously sound individual.

The recognition of these facts is important, not only from the eugenic point of view, but also for an etiologic study of many of our so-called organic psychoses. While we recognize that organic diseases are not hereditary, we must realize that there is a survivance of the hereditary tainting in each individual which will be given fuller play if faced with obstacles or traumata of an infectious or non-infectious origin. Kraepelin has adequately stated that the people themselves, their mode of life, and their habits play an important role causing variegated modes of reaction to "psychic insults."

Out of the chaos and confusion of the interpretation of the results obtained of the treatment of syphilitic meningoencephalitis,^{2,3} (general paresis) has come one salient point—namely, that no adequate study can be made of the various methods of treatment without a study of the affected individual's previous personality and the reaction type which he manifested during the initial psychosis and its subsequent course.⁴ It is with this thought in mind that investigators today are gradually interpreting their results

from the standpoint of six chief personality divisions

1. Simple dementing
2. Schizophrenic
3. Manic or expansive
4. Depressive
5. Agitated
6. Confused

It is gradually becoming evident that the results of treatment depend upon (1) personality type, (2) age of onset, (3) early treatment, and (4) type of treatment.

Various workers, among them C W Hutchings as well as Hinsie,⁵⁻⁸ have shown that the best prognosis occurs, as might be expected, in the confused, the manic or expansive type, and the depressed and agitated forms. The simple dementing types have the poorest prognosis. To illustrate some of the interpretive factors in the failures of various treatments of general paresis, a study was made of all the cases of this type present in one of the buildings caring for the chronic patients. Only cases which have had at least two years of treatment were included in this group. The majority of cases, however, had treatment for a much longer period and 1 has had continued hospital residency from as far back as 1917. All have had at one time fairly typical blood and spinal serology. However,

only the serology determined at this hospital is given in the statistical study. Practically all the patients have had at least 100 grams of trypanamide therapy intravenously as well as hismith intramuscularly, while some have had malaria or other hyperthermic methods of treatment. A record was made of the personality type at the time of admission. The present serology obtained in February, 1937, is also given, together with their present mental condition. Of the 17 cases quoted it was found that 12 were described on admission as the schizophrenic type, 3 of a manic type, and 2 of a grandiose type. At present the condition of some of these patients is described as slightly improved but the majority are unchanged or worse. At present, 15 are of the schizophrenic type and only 2 of a manic type. Ten are described as definitely unimproved and 1 is unchanged. (Table I.)

The remainder are slightly more amenable to the hospital routine. Fifty other similarly treated chronic cases were studied in the same way with essentially the same findings. It is noted that many of the individuals showed schizoid trends while others showed a mixture of schizoid and the grandiose or manic tendencies. With no exceptions all these cases have now changed into a definite schizophrenic pattern. There did not appear to be any parallelism between the mental picture and whether or not the treatment had been continued or interrupted. Neither did the treatment with malaria or other hyperthermic methods appear to cause any change in the ultimate picture to any greater extent than that of trypanamide therapy alone. The serology in most of them was improved and in the majority of cases the increased globulin had disappeared as had the increased cell count. Table I is markedly similar to that of a serologic study shown in Table II, a group of much improved patients who are now at home. It is also interesting to note that 1 case (Table I, case 3) was admitted to another hospital in 1917 and to the Rochester State Hospital in 1919. Apparently at this time it was not

the custom to take a routine Wassermann except in a suspected case. Two years ago this patient had a convulsion following which he developed physical signs of taboparesis. The blood and spinal serology were shown to be positive. This case is interesting in view of the oft-quoted statement that general paresis, if not treated, is uniformly fatal within eighteen to thirty-six months after its diagnosis. Examining this patient's history in retrospect, it can be seen that the symptoms would originally have been diagnosed as general paresis had the serology been determined. However, at that time only his personality reaction grouping was determined and he was classified as a case of dementia praecox, paranoid type. Today, however, he still maintains a fair personality, although his general reaction type is still the same.*

A review by Reed⁹ of 230 cases of general paresis following malaria therapy is interesting from the serologic viewpoint. His findings more or less substantiate those previously made,¹⁷ that the serology plays little or no part in the prognosis or interpretation of the results of the therapy. He presents a chart of 14 patients who had been paroled and who had apparently made a satisfactory adjustment at home. This is reproduced in Table II.

TABLE II

| ROSS-JONES TEST | PANDY TEST | CELL COUNT | WASSERMAN REACTION | COLLOIDAL GOLD REACTION | COLLOIDAL GOLD REACTION |
|-----------------|------------|------------|--------------------|-------------------------|-------------------------|

| 12 + | + | 20 | Doubtful | 0022100000 | 221000 |
| 13 + | + | 50 | +++ | 5354820000 | 221000 |
| 14 + | + | 53 | Weak + | 1122000000 | 100000 |

A study of Tables I and II shows no essential differences in spite of the fact that the first table is the serologic study of

* Since this paper was written, this patient died of general paresis confirmed by autopsy.

unimproved cases while the second is of those who would be placed in our improved or recovered group

From the first table it is quite obvious that the serology plays only a minor part in an evaluation of the methods of treatment. Seven of the 17 cases quoted have now a negative blood and spinal Wassermann and a negative or very slightly positive colloidal curve, and yet their mental status in the majority of cases is much worse than during the positive serology. In 3 cases there have been little or no changes while in the remainder there has been some improvement in the serologic picture but no improvement in the mental picture. The importance of the Wassermann test, especially the blood serology in neurosyphilis, is shown in Table III, taken from 250 cases of untreated late syphilis by DesBrisay.³

TABLE III

| | CASES | POSITIVE | PERCENT AGE |
|-----------------|-------|----------|----------------|
| Visceral | 18 | 18 | 100.0 |
| Latent | 49 | 40 | 93.8 |
| Cardiovascular | 20 | 17 | 85.0 |
| Osseous | 19 | 16 | 84.2 |
| Cutaneous | 22 | 18 | 81.2 |
| Mucous membrane | 10 | 8 | 80.0 |
| Neurosyphilis | 144 | 47 | 41.2 |

It is quite evident from a study of this survey that there is a more or less natural tendency to a negativity of the blood in neurosyphilis. Stokes maintains that only 60-70 per cent of positive reactions may be expected in treated and untreated cases of late syphilis as it passes through a general diagnostic clinic. It is therefore evident that as a diagnostic aid in latent and late syphilis the positive blood Wassermann reaction alone leaves much to be desired and puts a premium on the clinical knowledge of the disease, making necessary, in addition, more complex diagnostic methods such as provocative procedures and spinal fluid examinations. However, it must be emphasized that serologic tests are no aid whatsoever in the prognosis or the progress of treatment. It is with this thought in mind that the results of treatment by various methods are evaluated. As might be expected, results of cases

treated early show the most hopeful signs. In a group of such cases reported from the Buffalo State Hospital,¹⁰ over 50 per cent of the cases apparently showed a complete remission when treatment was instituted at least six months after the onset of the disease. In this study the personality factors are not mentioned. The results of treatment are based upon the improvement in the behavior pattern more than on the physical well-being. The following classifications are usually adopted

1 Complete Remission

Here apparently all abnormal psychotic trends have disappeared and the patient has returned to his former mental state. An additional criterion is that he has improved to such an extent that he is able to resume his former occupation or one of the same level. He must also be able to resume his former level in society. Should this definition of a complete remission be strictly adhered to, the number of cases falling into this group would be very small. It is difficult to estimate the previous level since most of the information must be obtained from members of the family or friends. In a similar way the behavior pattern after treatment is difficult to follow unless the individual is under the observation of a skilled psychiatrist most of the time, as little peculiarities which may be of vast importance are frequently dismissed as of no consequence by friends or relatives. It is also at times unfair to state that the person has not made a complete remission because he has been unable to return to his former position, since it must be recognized that patients as a rule are retained in the hospital for treatment for periods varying from one year to several years. This results in a difficulty in adjustment for a time. Also, because of present economic conditions it may be impossible to obtain a position equal to the former, especially if it is known that at one time he was in a hospital for treatment of the mentally ill.

2 Incomplete Remission

Here is included the large majority of patients who have improved enough physically and mentally to be able to engage in some type of useful occupation, either inside or outside of the hospital, but who have not improved to such an extent that they can return to their former occupations. There may be permanent defects such as lack of judgment or insight and also subsequent relapses. Another subgroup is a type which has made more physical gain than

psychiatric. This includes by far the largest number of patients in Table I in this article. The mental condition appears to be stationary for years although they are still in need of hospital care. As was quoted previously a large proportion of this group belong to the schizophrenic reaction type.

3. Unimproved

Here there is no improvement in the mental condition which becomes either slowly or rapidly worse in the same manner as may occur in cases which have had no treatment.

4. Death

Here death occurs during or shortly after treatment, frequently in a very malignant and rapid fashion.

The aims of the treatment may be briefly stated as relief of symptoms with an attempt to restore any individual to his usual standard or, failing this, to arrest or retard the process as well as to make the individual noninfectious. Serologic normality is only a byproduct of the treatment and not a guide to the value of the treatment. It is interesting to note that the two chief methods of treatment in vogue at present began in 1917 when Wagner Von Jauregg of Vienna published his first results with malaria and two other workers, Jacobs and Heidelberger of the Rockefeller Institute, first created an arsenobenzol compound called tryparsamide which had only a 25 per cent arsenic content but a low toxicity and a marked power of penetration into the nervous tissue. Since then a controversy has arisen as to the best methods of treatment. Analysis of results of the various workers must be viewed from several angles. There is always the personal equation to be considered, also varied opinions as to what constitutes a complete or partial remission. Since it is only recently that the results have been studied from the standpoint of reaction patterns, the factor of tissue destruction from old processes must also be considered. Statistics taken from literature of the last few years regarding the results of treatment therefore show considerable variations because of the numerous factors involved.¹¹⁻¹⁴ One worker reports results

of the malaria therapy alone in 100 cases and then compares it with another unselected group of 100 cases treated by both malaria and tryparsamide. This worker is in general agreement with other investigations in that he believes that the better results are obtained with the latter group. However, other workers report equally good results with various methods of artificial hyperpyrexia.¹⁵⁻¹⁷ The feeling is present that results depend to a great extent upon the selected clinical material. No one at the present time knows what a course of tryparsamide consists of. Some feel the 60 to 70 grams are sufficient while others give as high as 300 grams or more. Similarly, we have no clinical basis for claims made that a fever of 102½° F for seventy hours will accomplish as much as a higher fever for a more prolonged period. One worker (Dr S. L. Warren, Rochester, N. Y.) reports very good results in untreated cases with the use of the prolonged higher fever therapy followed by no chemotherapy. Some clinics prefer immediate malaria treatment while others give initial course of tryparsamide followed by tryparsamide and malaria.^{18, 19} Stokes²⁰ gives the following indications and contraindications for malaria therapy.

Indications

1. Early paresis and preparais in young robust persons
2. The same conditions in older patients without contraindications.
3. Presence of neurosyphilitic or other optic nerve disease contraindicating tryparsamide
4. Resistant nonparetic asymptomatic neurosyphilis (in late latency not early syphilis)
5. Where a reasonable trial of tryparsamide has failed (one year) and no contraindications to malaria appear
6. Optic atrophy (probably inferior to intraspinal therapy) and gastric crises persistent lightning pains when not otherwise contra-indicated.

Contraindications

1. Decentralized inexperienced control and inadequate facilities (not a practitioner's method)
2. Unsatisfactory strain of malarial organism.
3. Donor of same blood group as patient (Wagner Von Jauregg)

4 Old age Age limit should be based on physical status rather than years (probably not over 45)

5 Definite cardiovascular disease, especially coronary and myocardial and including arteriosclerosis

6 Pulmonary tuberculosis, latent or active

7 Chronic alcoholism

8 Marked diabetes (mild is not)

9 Severe anemia

10 Obesity

11 Persistent thymus

12 "Galloping" paresis

13 Advanced tabes with severe ataxia, decubitus, pyelonephritis

14 Pregnancy

15 Kidney disease.

16 Marked hepatic disease or insufficiency, or splenic disease

17 Severe debility

18 "Last stages"

Discussion

1 *Advantages of Malarial Therapy*—On the whole, probably the highest effectiveness, risks disregarded, of any single form of treatment for neurosyphilis, accomplishes much in a short time, institutional features control therapeutic flare-up without family and social difficulties, places responsibility and control in hands of experts, the best single chance for results in cases un-co-operative and difficult to control

2 *Disadvantages of Malarial Therapy*—A "center" or institutional method for the experienced only, not always available, mortality 0.5 to 10+ per cent, temporary dislocation of occupation and economic status, some stigmatization, difficulty of maintaining safe strains of organism in small institutions, discomforts of stormy course, not adapted to the debilitated, complicated case

Reviewing the results obtained from malaria therapy in 60 cases of general paresis, Russman²¹ reported 27.7 per cent complete remissions and noted that Raynor had reported a normal spontaneous remission of 3.5 per cent. There were 12.9 per cent of his patients who belonged to the group of partial remissions while 18.5 per cent were classified as improved. The unimproved group consisted of 22.2 per cent

He again shows that the serologic changes were not consistent with the clinical changes but demonstrated that there was a tendency to weaker Wassermann and Kahn reactions after treatment with a lessening of the cell count and a decrease in globulin. In most of his cases the colloidal gold curve dropped and became less typical. This was well shown in the writer's cases. It is interesting to note that a review of the literature shows a death rate varying from a fraction of a per cent to as high as 12 per cent in the series of 580 cases reported by Karnosh and Williams of the Cleveland State Hospital.²² Kuhns²³ surveyed the present status of hyperpyrexial therapy in the various state hospitals in Illinois and his tables are herein reproduced (Tables IV and V).

TABLE IV—EVALUATION OF ARTIFICIAL PYREXIA IN 500 PATIENTS

| THERAPY | PATIENTS PROVED | IM- 52% | UNIM 28% | PROVED WORSE 20% |
|------------------|-----------------|---------|----------|------------------|
| Typhoid vaccine | 100 | 52% | 28% | 20% |
| Sulfur in oil | 100 | 58% | 21% | 21% |
| Malaria | 100 | 60% | 20% | 14% |
| Diathermy | 100 | 72% | 11% | 17% |
| Electric blanket | 100 | 78% | 15% | 7% |

TABLE V—DIFFERENT METHODS OF FEVER TREATMENT AND RESULTS OBTAINED

| THERAPY | PATIENTS PROVED | IM- 58% | UNIM 30% | RE 4% | DIED 8% |
|------------------|-----------------|---------|----------|-------|---------|
| Malaria | 96 | 08% | 16% | 4% | 12% |
| Sulfur in oil | 60 | 35% | 55% | 0% | 10% |
| Electric blanket | 40 | 00% | 28% | 12% | 0% |
| Typhoid vaccine | 27 | 74% | 26% | 0% | 0% |
| Combined forms | 24 | 46% | 42% | 4% | 8% |
| Total | 247 | 58% | 30% | 4% | 8% |

Hutchings⁵ in a study of 182 cases reported 66 as much improved, 54 as improved, 62 as unimproved, and of the group 25 went home. He studied the personality type and found that 82 per cent of the confused type and 67 per cent of the depressed type had been discharged while only 20 per cent of the schizophrenic type or simple type were discharged following treatment with malaria and tryparsamide. It is interesting to note that in 56 of these cases the spinal fluid cleared up completely while in 72 it showed some improvement. However, in these groups less than

half were discharged. Paradoxically, in 19 cases in which the spinal fluid had not changed, 17 were discharged.

Paulian, Fortunesco, and Tudor of Bucharest²⁴ report the results of malaria in 100 cases. There were 40 per cent remissions, while 42 per cent showed some improvement.

Barnacle, Ebaugh, and Ewalt of the Colorado Psychopathic Hospital²⁵ report the results of the hyperpyrexia treatment of two series of patients. A group of 30 were treated with the Kettering hypertherm at a temperature of 105 F to 106 F for an average of 44.5 hours and 10.4 treatments per patient. In addition to this treatment each patient was given 2 grams of tryparsamide at the height of each fever and following the hyperpyrexial treatment, tryparsamide was given at regular intervals, in 3 gram doses. Another group of 30 was treated with benign tertian malaria. There was an average of 9.9 febrile periods per patient and an average number of 8.2 chills. These patients were later given neoarsphenamine and tryparsamide. In the first group treated by mechanical hyperpyrexia and tryparsamide, 70 per cent of the patients appeared benefited, while in the second group treated by malaria and tryparsamide, 64 per cent of the patients were improved. The results showing only a difference of improvement in 2 cases cannot be interpreted as favoring one method or the other.²⁶⁻²⁸

The various results quoted would indicate that there probably is very little difference in the results obtained by the various methods of hyperpyrexia, whether produced by malaria or by other types of hyperpyrexial methods, i.e., diathermy and heat cabinets. It is, however, felt that chemotherapy should be given following all the pyrexial treatments. A review of the literature would seem to indicate a consistent marked improvement when this mode of procedure is used.*

Summary

1 The results of various methods of treatment in neurosyphilis are difficult to evaluate unless viewed from the standpoint of personality patterns, the duration of the disease, and the type of treatments.

2 Hyperpyrexia and chemotherapy appear to be the most efficient present methods of treatment.

3 Serologic and clinical changes show no parallelism. The laboratory tests for syphilis should not be used as a prognostic indication or a guide to further treatment. In all cases the present accepted method of treatment should be carried out to the full extent, even if the patient has shown a marked clinical or serologic improvement before the treatment is called adequate.

4 A study of the cases of general paresis who have been in the chronic service of a State Hospital for at least two years after fairly adequate treatment shows a preponderance of schizophrenic reaction pattern types. It is also noted that the majority of these showed a schizoid trend at the time of admission.

A HOME VIEW OF THE CITADEL

The award of the highest American honor for a 1938-made film in the English language to the production adapted from Dr A J Cronin's "best seller" has naturally a special interest for the medical profession, remarks *The British Medical Journal*, because of the predominantly medical implications of the plot. Exactly how far, if at all, the author of the book intended his work of fiction to be regarded as a tract has been the subject of widely differing views.

The public greedily absorbed the notion, probably fostered by the publisher and his advertising agents, that it was meant as a genuine and savage satire on "Harley Street" and all its ways—by which term they understand the whole body of London consultants, regardless of the fact that the geographical area in question houses types of practitioner as far asunder as the poles in scientific distinction and in devotion to the public weal.

The public was probably wrong, just as Dr Cronin would not pretend to have produced a literary masterpiece or an important work of propaganda. He is first and foremost a storyteller—and at the moment has few superiors in that craft in England, and in *The Citadel* he used his medical training and experience to aid him in telling a story which has had a most remarkable success. Fiction is not evidence on oath, and we cannot demand of a medical novelist that he shall subordinate his plot or his "local colour" to accuracy in matters of detail.

The main fault with this very readable book was the way in which the exceptional was over-emphasized so as to make it appear the usual. When the film magnates, in their turn, commissioned a producer to turn a novel into a talking film, their aim is neither instruction nor political propaganda but the more commercial aim of amusing and interesting their patrons, these

include all classes, and among them the unsophisticated are in an immense majority. It is box-office returns, not art or literature, or education or social betterment, that the film industry is after, whether in the process the public gets right or wrong impressions on this or that subject is of small importance compared with the financial results, which in turn depend on tickling the ears (and eyes) of the groundlings.

Thirty years or more ago one remembers that Mr Somerset Maugham (a medical man) put on the stage a scene in which a young consulting physician in "Harley Street," hard put to it because his practice was very meager, contemplated scattering orange peel on the pavement outside his rooms in the hope of getting some sprains or broken legs to treat as a result. The playwright, of course, had his tongue in his cheek, as the medical members of his audiences knew, but the rest of the world saw nothing abnormal in the incident. Similarly, the film version of Dr Cronin's book abounds in glaring and much more serious medical solecisms, which will go unperceived by the laity, though his professional brethren detect them easily enough.

The question is not whether this film is well produced and well acted, but whether it gives a distorted view of medical life and medical morals, and, if so, how far it is calculated to lower our profession in the eyes of the public. Its qualities as a film are a matter for cinema critics, they have been discussed in all the lay papers and do not much concern doctors as doctors. In our view declares *The British Medical Journal*, *The Citadel* film, apart from its absurdities, gives a false impression of British medicine and British doctors, which in the long run will do harm unless the public regard it merely as entertainment. Anything that lowers prestige by so much lowers confidence, and confidence is the chief element in the doctor-patient relationship.

TIME TO KICK

Our businesses, our recreations, our everyday existence, our every move, almost, have all been subjected to regimentation. But we should kick,

and kick plenty, when our lawmakers try to subject even our health and physical well being to regimentation.—*Goshen (N Y) Independent*

CARCINOMA OF RECTUM AND COLON

Early Diagnosis and Treatment

FRANK C. YEOMANS, M.D., F.A.C.S., New York, N. Y.

Symptoms

THE colon is divisible into two segments, right and left, which have different embryology, anatomy, and function. The right colon, as far as the middle of the transverse colon, together with the small intestine, is developed from the midgut, its blood supply is from the superior mesenteric artery which is the artery to the midgut, and its function is digestion and absorption. The left colon, left half of transverse, splenic flexure descending and pelvic colon, is derived from the hindgut, and is supplied by its artery, the inferior mesenteric. The function of the left colon is storage and propulsion of the fecal column.

These differences in origin and function give rise, in general, to different sets of symptoms which vary with the situation of the neoplasm and the extent of involvement.

Early symptoms are usually vague but have serious import.

Carcinoma of Cecum and Ascending Colon—As the bowel lumen is largest in this segment of the colon and its contents liquid, an early, small tumor may give few or no symptoms unless it encroaches upon the ileocecal valve. Discovery of a tumor by the patient or examiner may be the first sign.

Discomfort for several months in the right lower abdomen is the chief early complaint in 90 per cent of patients. Recurring attacks of pain frequently lead to the erroneous diagnosis of subacute or chronic appendicitis. The appendix had been removed without benefit in 15 of 100 cases studied by Priestley and Bergen.¹ Reflex disturbances to the upper portions of the digestive tract causing anorexia, fulness after meals and eructations, frequently divert attention from the primary lesion. Diarrhea and

constipation are not characteristic and gross bleeding is seldom observed. However, in advanced lesions anemia, weakness, and loss in weight may suggest pernicious anemia until the blood picture of secondary anemia directs attention to the right colon.

Transverse Colon—Due to the narrower lumen of this segment and its more formed content, intestinal colic and pain, relieved by the passage of gas or feces, is a characteristic early symptom. With increasing involvement, constipation is progressive and is an important symptom in persons of previous normal bowel habit. Complete obstruction is prone to supervene, especially when the annular constricting growth is at the splenic flexure. The latter is seldom palpable but a mid colon tumor, which may be felt early in 50 per cent of cases as a movable mass, may later involve the stomach in a rather fixed tumefaction and cause severe gastric symptoms. Bleeding and anemia occur in about 20 per cent of cases. Massive hemorrhage was the initial symptom in a man, age 52, whom I saw with cancer of the transverse colon.

Descending Colon and Sigmoid—Disturbance of motor function occurs in three fourths of the cases. Progressive constipation is usual with periods of diarrhea in about 20 per cent, less often alternating constipation and diarrhea. Later, obstruction develops with classic symptoms. Pain of some type is usual, manifesting itself at first as discomfort in the left lower quadrant of the abdomen and radiating across to the right side. Rectosigmoidal involvement usually ends in stenosis evidenced by abdominal distention, borborygmi, frequent small bowel evacuations and reflex digestive disturbances. Gross blood in the stool occurs in

50 per cent or more of cases. Anemia and weight loss are less than for neoplasms of the right colon. A tumor of the descending colon, especially in a stout person, is rarely palpable but approximately one-third of those in the sigmoid can be felt. The error of diagnosing feces impacted above an obstructing tumor as a neoplasm is rather common.

Rectosigmoid and Rectum—The earliest symptoms are constipation, bleeding, and discomfort in the rectum. Onset of obstinate constipation in a person of cancer age, urgency to defecate on rising in the morning, with no result or only the passage of flatus and blood-tinged mucus, or a vague feeling that something is radically wrong in the lower abdomen, or a feeling of fulness and obstruction in the rectum, occurring separately or in combination, form a symptom-complex that is present in nearly every case of carcinoma of the rectosigmoid or rectum. A tumor in the large rectal ampulla may be virtually "silent" until far advanced. Tenesmus occurs only with neoplasms situated low in the rectum. Indigestion, anemia, and weakness are not characteristic of the early stages of malignancy of the distal bowel.

In summary. The symptoms of early malignancy of the colon are vague—for the right colon "indigestion," abdominal unrest, intestinal colic, and secondary anemia, for the left colon, progressive constipation, spurious diarrhea, gas pains, and gross rectal bleeding. The symptom-complex of carcinoma of the rectosigmoid and rectum is distinctive.

Diagnosis

Error in diagnosis of colonic lesions, as proved by operation or autopsy, ranges from 20 to 40 per cent.

The two chief reasons why there is an average interval of six to eleven months after the earliest symptoms until the patient with cancer of the large bowel comes under treatment are: first, failure of the patient to obtain competent medical advice until the growth is far advanced, as evidenced by pain, bleeding or obstruction, and, second, omission of a thorough

examination by the physician *first* consulted.

The *periodic health examination*, especially after the fortieth year, should include palpation and endoscopy of the terminal bowel. Early cancer would thus be discovered and the precancerous adenomata detected and destroyed before they had undergone malignant degeneration.

The early symptoms noted, when elicited while taking a complete history of the patient, should impress the clinician with the possibility of cancer.

Unfortunately, several other organic lesions of the large bowel give symptoms and signs simulating malignancy. Notable among these are nonmalignant tumors, appendiceal abscess, bleeding internal hemorrhoids, segmental cicatrizing enteritis, chronic ulcerative colitis, diverticulitis, lymphosarcoma, and the specific granulomata, i.e., tuberculosis, syphilis, amebiasis, actinomycosis and venereal lymphogranuloma.

Examination

It is essential that the physical examination be methodical and in the following order:

- 1 General and abdominal. In women, vaginal examination should precede rectal palpation to determine the size, position, flexion, and mobility of the uterus, and the state of its adnexa, the condition of the rectovaginal septum, and to detect pathology in the pouch of Douglas.

- 2 Digital palpation of the rectum, which detects practically 100 per cent of rectal carcinomas. As a result of neglect of this simple procedure, many patients are treated for months for "dysentery" or "bleeding piles" without having a proper examination. From 10 to 18 per cent of patients with carcinoma of the rectum or rectosigmoid have been treated or operated upon for hemorrhoids within the period of active cancer symptoms. The peritoneal culdesac should always be palpated. Detection of induration at this site frequently indicates a hopeless metastasis from a carcinoma higher in the

abdomen, usually of the stomach or colon

3 Proctosigmoidoscopy reveals ulcerative lesions, strictures, benign and malignant growths of the rectum and, in about 75 per cent of cases, similar lesions of the distal pelvic colon. Material is obtained for smears and cultures and biopsy specimens are taken when indicated. Failure to pass the tube through the rectosigmoid is usually due to an angulation caused by adhesions of the sigmoid or an organic obstruction—stricture, neoplasm, or diverticulitis—the nature of which can frequently be determined by the endoscopy.

4. Roentgen ray study. The data obtained by sigmoidoscopy should be given to the roentgenologist *before his examination*. The x-ray cannot and should not be expected to demonstrate ulcers, small benign tumors, or early carcinoma of this difficult bowel segment situated within the bony pelvic girdle which is so accessible to direct inspection. However for the colon proper, fluoroscopy and roentgenography with the barium enema is the most valuable diagnostic procedure for detecting carcinoma and other lesions of the colon or excluding them from the picture.

5 Laboratory. Routine laboratory tests may include (a) urinalysis, (b) routine blood picture and type, (c) Wassermann test of the blood for syphilis, (d) sedimentation rate, (e) Frei antigen skin test for venereal lymphogranuloma in suspicious cases, and (f) examination of feces for gross and occult blood, parasites, and ova.

Differential Diagnosis—Right Colon

The clinical course may greatly aid in the differentiation of the commoner conditions of the *right* colon, although the co-existence of multiple lesions must be kept in mind.

In *carcinoma*, weakness, weight loss and secondary anemia are progressive.

The roentgen filling defect is usually irregular and its margins definitely rough.

Hyperplastic tuberculosis has a predilection for and frequently involves a long

stretch of the ileocecum and ascending colon, and occurs especially as a secondary manifestation of pulmonary tuberculosis in persons under the 'cancer age' of forty years. Of 66 cases reviewed by F. C. Herrick, 54 (82 per cent) occurred before the fortieth year. Hyperplastic tuberculosis has a protracted course, thus contrasting with the steady progress of carcinoma.

Actinomycosis of the abdomen is rather common in some parts of Europe and in the northwestern section of the United States. In New York City the disease is so rare that it may not be suspected and the correct diagnosis not be made until the chronic inflammatory process is far advanced, and then only by biopsy, at operation, or at autopsy. During the six-year period (1929-1935) the records of the Department of Health of the City of New York show only 9 cases of actinomycosis, only 1 being abdominal. The 2 cases I have seen were (1) a girl, aged 19 years, with involvement of the appendix and rectum, and (2) a man, aged 32, with primary involvement of the cecum and secondary abscess formation in the right lobe of the liver and the right lung. Cecal actinomycosis tends to invade the anterior abdominal wall and form more fistulas. The course is chronic, with febrile after secondary infection has occurred. Discovery of the specific actinomycotic granules in scrapings from a sinus clinches the diagnosis.

Frequently appendectomy is performed in tuberculosis and actinomycosis of the cecum, the process being discovered after the fecal fistula formed several months later.

Localized cicatrizing ileitis is a tender tumefaction in the right quadrant, is marked by nodular epistodes resembling actinomycosis and usually presents a narrow roentgenogram—a narrow men of the terminal ileum.

An amebic granuloma of any segment of the large intestine for its shorter duration frequently mimics carcinoma.

this erroneous diagnosis resections have been performed, nearly always with fatal issue. Roentgenograms do not show the clear-cut picture of carcinoma. From my experience with 4 cases of amebic granuloma, 1 of the transverse colon and 3 of the rectum, I feel convinced that proctosigmoidoscopy is invaluable in obtaining from the pathognomonic ulcers material in which the specific amebas may be demonstrated on the warm stage of a microscope, thus establishing the diagnosis.

Localized lymphosarcoma often presents a baffling picture of intestinal colic and obstruction, without bleeding. When this condition is suspected, deep roentgen ray therapy will temporarily shrink the lymph nodes, ameliorate symptoms, and thus suggest the true nature of the lesion.

Appendix—Either of two pathologic conditions of the appendix may produce a tumefaction. One is a large, thick, retrocecal appendix, frequently tuberculous, adherent to the posterior abdominal wall, the other an appendiceal abscess, enlarging slowly, with or without slight rise in temperature and leukocytosis. In either instance the patient is usually younger than the patient with cancer.

Differential Diagnosis—Left Colon

In the left half of the colon, *diverticulitis of the sigmoid* is the chief organic lesion to be differentiated from cancer. The obstructive and other symptoms are much the same, but gross bleeding is rare in diverticulitis unless cancer coexists. There is a slight rise of the evening temperature and moderate leukocytosis, and the tumor is not fixed unless it has fused by inflammatory adhesions into the anterior abdominal wall or the bladder. The x-ray study shows a spindle-shaped filling defect, due in part to spasm, and usually shadows of extra-luminal diverticula which confirm the diagnosis.

The occurrence of cancer in patients beyond the fortieth year having diverticulosis or diverticulitis is not unusual. The coexistence has been observed in from 4 to 30 per cent of operated cases.

The association seems to be coincidental and not causal. The x-ray and proctoscopy are our chief reliances for their recognition.

Hyperplastic Tuberculosis—The site of the lesion in the 100 cases collected by Lockhart-Mummery was cecum or cecocolon, 90, whole colon, 4, sigmoid, only 6. No tuberculous foci were found elsewhere in 76 of these cases, but the lungs of 18 showed tuberculous lesions. The majority of cases develop between the twentieth and the fortieth years of life. The correct diagnosis of hyperplastic tuberculosis of the sigmoid is seldom made before surgical intervention to relieve obstruction or for the removal of a tumor, presumably malignant.

Differential Diagnosis—the Rectum

As regards carcinoma of the rectosigmoid and the rectum, two outstanding facts are not fully appreciated. First, the neoplasm is in a field accessible to both palpation and inspection, and, second, that approximately 75 per cent of rectocolonic malignancies involve this bowel segment.

Our statistics at the New York City Cancer Institute illustrate well the segmental incidence of carcinoma of the digestive tract as determined by the accurate diagnosis on discharge. For the years 1931-1937, inclusive, the patients discharged numbered 4,673.

Alimentary canal involvements were esophagus 148, stomach 484, cecum 16, colon 46, sigmoid and rectosigmoid 78, rectum 360, anus 4, a total of 1,136. Of the 500 malignant neoplasms of the large bowel, 360, or 72 per cent, were in the rectum.

This predominant incidence of cancer in the accessible terminal bowel places a grave responsibility upon the clinician for its early detection or the discovery of other lesions giving rise to similar symptoms. A carcinoma of the rectum is felt on digital palpation as (a) a polypoid, intraluminal growth of small or large size, at onset movable with the rectal mucosa, and relatively benign in that few or no

lymph nodes are involved, (b) a crater like excavated growth with an indurated, ulcerated base and nodular margins, infiltrating the musculature and permeating the lymphatics early, and (c) an annular constricting growth with indurated base and nodular margins, rather definitely limited to the bowel wall and tending to produce early stenosis, especially in the rectosigmoid

These details of size, position, mobility or fixity of the tumor, its involvement of adjacent organs and metastasis, are all prime factors in determining operability and prognosis

Direct inspection through the proctoscope reveals the findings of palpation which in doubtful cases are confirmed by biopsy

Unless they can be extruded, *bleeding internal hemorrhoids* are recognized not by palpation but by anoscopy, which is always to be followed by sigmoidoscopy to rule out other sources of bleeding before the hemorrhoids are treated

This procedure differentiates *simple* polypoid tumors, such as single and multiple adenomata, and the rare villous papilloma.

Inflammatory stricture generally presents as a smooth, funnel shaped, cicatricial, annular constriction, usually felt just above the anal canal. Its surface is ulcerated, its course is longer than that of cancer and, in the vast majority of cases the Frei antigen skin reaction is positive, thus proving the lesion to be venereal lymphogranuloma. The Frei test should be done in every case of stricture or ulceration of the rectum, and the Wassermann blood test in every case of tumor, stricture, or ulcer

If a thorough clinical and laboratory study does not lead to a satisfactory conclusion, laparotomy is indicated, as the risk of diagnostic incision is minimal compared to the policy of 'watchful waiting' until an operable lesion has reached a hopeless stage.

Prognosis

The operative prognosis of lesions of the right colon is technically better than for

those of the left because the blood supply through the ileocolic artery to the right half is more constant, obstruction is seldom present and the bowel contents are less septic. In practice, results may be the reverse

Metastasis from rectocolonic carcinoma occurs relatively late but it increases with the duration of the disease. The poor late operative results, due to visceral metastases are in direct ratio to lymphatic permeation and intravascular (capillaries and veins) invasion². Regional lymph node permeation occurs later from right than from left colonic cancers and metastases to the liver are comparatively rare. Since dissemination occurs relatively late, early discovery and wide removal of the primary growth afford the possibility of cure in many cases

The American College of Surgeons has complete records of a total of 29,195 five year cures of proved cancer of which 3,151 are of the colon and rectum⁴. Although these figures represent only a fraction of five-year cures that have been obtained, they are very significant and encouraging. They should serve to supplant optimism for the pessimism all too prevalent in both the professional and lay mind. Pessimism is based largely on the inevitably poor results of late and emergency operations.

Treatment

Limitations of time make only the briefest outline of treatment possible. Radium, the cautery, and surgical diathermy are limited in their application to tumors below the peritoneal reflection and are indicated chiefly for radically inoperable carcinomas of the rectum. The accessible rectal carcinomas are usually grade II and radium resistant, while the rectal mucosa is radium sensitive.

When warranted by the general condition of the patient, radical surgical excision in one or more stages including the adjacent zones of lymphatic spread, yields the best results and the highest percentage of five year cures

For tumors of the cecum, ascending

colon and hepatic flexure, a right colectomy is performed with end-to-side or lateral anastomosis of the terminal ileum and the transverse colon, thus establishing continuity

With tumors of the left colon and splenic flexure which tend to obstruction, the radical excision in one or two stages is usually preceded by a cecostomy to decompress the bowel. A small cancer in a long sigmoid may then occasionally be resected with end-to-end anastomosis. As a rule a safer procedure is the exteriorization maneuver in two or three stages (Paul, Mikulicz)

For a neoplasm situated in the pelvic colon, the bowel may be divided between clamps below the growth. The distal end is inverted, the tumor-bearing segment excised, and a permanent colostomy established with the proximal end. This procedure has yielded me excellent results, and several patients are well without recurrence over five years. Rarely the proximal end can be invaginated into the rectal stump and sutured, thus establishing continuity, after the method of Balfour

For cancers of the rectosigmoid and upper rectum the Miles procedure is the best—permanent sigmoidostomy with excision of the entire bowel beyond the stoma in one stage

Rectal growths, the upper margin of which can be reached by the finger, can be removed safely by perineal excision, with or without permanent colostomy. Perineal excision is especially indicated and gives good results in the aged, the debilitated, and in obese patients

Epithelioma of the anus should be implanted with gold seeds of radon and proctectomy performed six weeks later. Irradiation alone is successful in some instances. Two of my patients treated with radium for epithelioma over ten years ago are well

Summary

1 The early symptoms of cancer in each segment of the large bowel are presented

2 The differential diagnosis of other lesions preventing similar symptoms is discussed

3 The methodical sequence of the physical examination is stressed and the required laboratory data stated

4 Anatomic conditions favoring operation are mentioned and metastases as affecting the late prognosis are noted.

5 The operative procedure indicated for cancer of each rectocolonic segment is outlined briefly

Discussion

Dr William H. Stewart, *New York City*—The statement has been made, which is probably true, that lesions of the colon are more often overlooked roentgenographically than in any other portion of the gastrointestinal tract. Any attempt to discuss the roentgenographic aspect of malignancies of the entire colon in the time allotted would obviously be impossible. I therefore have limited my remarks to the pelvic portion.

The differential diagnosis of lesions of the sigmoid presents one of the most important and of ten one of the most difficult problems in roentgenology. It is important because cases of carcinoma and diverticulitis of the sigmoid are of frequent occurrence and important because the treatment in the two conditions is so different that serious consequences result in almost every case where an error in diagnosis is made.

In many cases the differentiation of benign and malignant colon lesions offers unusual difficulties, as carcinoma may be present in a patient with diverticulitis and in another patient inflammatory changes secondary to a diverticulitis may produce a tumor mass which has many, if not all, of the roentgen features of carcinoma

It is unreasonable, therefore, to expect a diagnosis in every case on the x-ray studies alone. The problem is a difficult one and the roentgenologist is entitled to all the clinical and laboratory information available, in addition to his roentgenographic information. In almost all cases when all of the available material is considered, a

CANCER OF THE SIGMOID

- 1 Canalization
- 2 Mucosal pattern destroyed
- 3 Filling defects show as lobulated cauliflower masses with irregular ragged lumen and showing fingerprint deformity
- 4 There are two special types. The napkin ring deformity with minimum involvement and the massive deformity with crater formation
- 5 Usually a sharp sudden demarcation between normal and pathologic involvement
- 6 Haustral markings destroyed
- 7 Persistent unilateral deformity in some types
- 8 No evidence of diverticuli
- 9 Constancy to the character of the deformity
- 10 Rigidity with fixation and a frozen mass
- 11 No masses of barium seen outside the lumen of the gut
- 12 Usually intraluminal unless accompanied by perisigmoidal inflammatory mass
- 13 The sigmoid is liable to maintain its patency through canalization and fixation. The proximal colon is dilated. Sudden destruction may occur
- 14 Spasm of the colon is more likely to occur at the site of the lesion

DIVERTICULITIS

- 1 Not present
- 2 Mucosal pattern still incompletely seen
- 3 Filling defect consists of a serrated irregular picket fence appearance
- 4 Massive involvement. No crater formation. Never napkin ring deformity
- 5 No distinct demarcation between normal and pathologic involvement
- 6 Haustral markings still in evidence. Pockets at depth of indentations widened
- 7 No unilateral deformity in any type
- 8 Bud like shadows present indicating diverticuli
- 9 Changing character to the defects
- 10 Maintenance of flexibility
- 11 Masses of barium may be seen outside the outline of the colon from ruptured diverticuli
- 12 Extraluminal. The lesion is always in the wall or in the perisigmoid structures
- 13 Intestinal obstruction from inflammatory swelling and edema frequently occurs. Dilatation of the proximal colon not so extensive
- 14 Spasm of the colon is more frequently seen away from the site of the lesion

reasonable diagnosis can be made. Before arriving at a definite conclusion however I should like to emphasize the necessity of obtaining adequate film studies. The tendency is to limit the roentgenographic examination in the diagnosis of colonic lesions while in gastric investigations unlimited films are the rule. There is no set pattern for the colon and there is consequently no routine position or set of positions that will yield diagnostic films. Every patient requires careful individual consideration and fluoroscopic examination. The x ray apparatus should be equipped with a spot film device which permits the production of films at any time during the fluoroscopy. In many patients a single film of the sigmoid made with the patient in the left posterior supine oblique position will yield all the information necessary. This must be made with the bowel only partially filled and the position carefully checked by fluoroscopy. Just any left posterior oblique of the sigmoid will not do. In some cases five or six films of this region are not too many to establish a diagnosis. If only supine or prone films are taken or if the entire bowel is filled before the sigmoid studies are made redundancies are almost sure to obscure a portion of the sigmoid. In fact, one of the reasons we miss is that small lesions in the sulcus of the haustral contractions are overshadowed by the distended portion of the bowel.

The fluoroscopic examination is not only of importance as far as positioning is concerned. Palpation with the direct vision thus afforded can give much information as to tenderness fixation of the bowel and location of tumor masses.

In the differentiation between benign and malignant lesions of the sigmoid we have made the above comparison.

Acknowledging the vast superiority of the proctoscopic over the roentgenographic examina-

tion in lesions of the rectum nevertheless in pathology of the rectosigmoid and sigmoid the roentgenographic findings are often much more satisfactory than those discovered by the sigmoidoscope. Sigmoidoscopy requires skill and experience. Not everyone can pass a sigmoidoscope satisfactorily and recognize what he sees. However as the author states the roentgenologist and surgeon should work hand in hand in an endeavor to make a diagnosis which is difficult at the best.

Dr Henry W. Cave, New York City—There are many points worthy of comment in this excellent presentation of Dr. Yeomans.

He has emphasized and rightly so the symptoms and signs of early malignancy of the colon and rectum. He has stressed the vague symptoms of early growths of the right colon—progressive constipation, spurious diarrhea, gas pains, and gross rectal bleeding that point to left colon involvement. The symptom-complex of rectosigmoid and rectal growths he emphasizes is distinctive. My only comment on this section of his paper is that a large percentage of patients suffering from this disease of the colon, rectosigmoid and rectum in the early stages complain of nothing more than a feeling of abdominal discomfort, irregular bowel movements, and, in some, bleeding.

The three most valuable aids in the diagnosis of cancer of the large bowel and rectum are (1) Digital examination which in many instances is more satisfactorily carried out with the patient in the squatting posture; there have been many tumors of the lower sigmoid that have been missed because the patient was examined in the Sims or in the knee-chest positions. (2) The proctoscope is invaluable in determining the site, the size of the growth and in obtaining sections

for microscopic study which should be done in every instance, and should the first biopsy return negative, other specimens should be obtained (3) Fluoroscopy and x-ray study following barium enema is absolutely necessary if early growths of the cecum, ascending, transverse, and descending colon are to be recognized

As Dr Yeomans has pointed out, "from 10 to 18 per cent of the patients with carcinoma of the rectum or the rectosigmoid have been treated or operated upon for hemorrhoids within the period of active cancer symptoms" Should not a barium enema be given *every* patient who comes in complaining of a bloody discharge from the anal opening, no matter what they or their medical adviser think is the origin? May I re-emphasize the importance of turning over to the roentgenologist the data obtained by sigmoidoscopy In some instances, let it be stated that cancer of the colon and sigmoid is discoverable only when roentgenograms have been taken in the various oblique positions

The opportunity will now be taken to emphasize important features which have proved beneficial in our hands in the treatment of cancer of the colon and rectum

(1) Preoperative preparation, at least one week, should be required in properly preparing these patients for operation This in detail consists in cleansing the bowel thoroughly with Epsom salt, one-half an ounce twice a day, rectal and colonic irrigations with warm saline solutions, intravenous 5 per cent glucose in saline 2,000 to 3,000 cc daily, and low or nonresidue diets Three days prior to operation the cleansing process may be stopped, lead and opium pills, and paregoric, one dram, three times a day may then be administered with the idea of constricting the bowel, making it

technically easier to handle at the time of operation We are convinced that the mortality rate will be reduced if these measures are carried out preoperatively

(2) The employment of cecostomy for decompression purposes is of extreme importance if the slightest obstruction is present In a recent article by Sir Hugh Devine in the February number of *Surgery* he has brought forth the most hopeful procedure of so called operation on defunctioned distal colon His plan is through a small upper right rectus incision to explore the liver, to establish a complete diversion of the fecal current in the transverse colon, to then later treat the left colon by warm irrigations, and in this way prepare the completely disfunctioned colon for operation, and in growths of the left colon and rectosigmoid he has been able to resect with restoration of the fecal stream

During the last two years following Cattell's suggestion we have made an attempt to close the perineal wound following combined abdomino-perineal resection of the rectum and we believe unquestionably it has shortened the convalescence of these patients We believe the ideal operation for growths in the right colon is a two-stage procedure in the majority of instances side-to-side or end-to-side ileotransverse colostomy, later, at a second stage, resection We believe that the safest and most satisfactory procedure on the left colon is an exteriorization method, provided that the entire gland bearing area can be removed Although the Lahey two stage operation for cancer of the rectum is not only helpful but necessary in the larger growths, there is unquestionably a definite trend among the majority of rectal surgeons toward the combined abdomino-perineal resection in one stage after the Miles technic

441 FOREIGN DOCTORS FAIL IN STATE TESTS

Results of the State medical examinations for 1937-38, announced January 28 by the State Education Department, showed that of 1,063 foreign doctors who tried the tests, 441 failed to pass According to the department, 1,836 candidates took the examinations—1,063 from foreign schools, 285 from schools of other states, and 488 from New York medical schools

The report showed that 55 per cent of the New York educated doctors failed in the tests and 24.9 per cent from other states failed

Listed by country, number of candidates, and

number of failures, results of the examinations follow

Austria, 112 candidates, 35 failures, Germany, 422 candidates, 210 failures, Czechoslovakia, 12, 9 failures, England, 12, no failures, France, 36, 14 failures, Hungary, 12, 8 failures, Ireland, 7, 5 failures, Russia, 10, 9 failures, Scotland, 88, 14 failures, Switzerland, 181, 66 failures, Syria, 2, no failures, Italy, 103, 58 failures, Turkey, 1, 1 failure, Cuba, 2, no failures, Canada, 62, 11 failures, Mexico, 1, 1 failure

CHANCROID A COMPARATIVE STUDY OF THE ITO TEST MADE WITH THREE VACCINES

HARRY C SAUNDERS, M D, ORLANDO CANIZARES, M D, and
REUBEN FRANK REIDER, M D, New York City

(From the Department of Dermatology and Syphilology New York University College of Medicine and the Dermatologic Service of Bellevue Hospital Service of Drs Howard Fox and Edward R Maloney)

THE Ito test, performed with vaccines of Ducrey streptobacilli injected intradermally, has been used extensively in foreign countries, since its discovery and has been universally considered satisfactory

In Europe, the most widely used Ducrey vaccine is the French commercial preparation, "Dmelcos," which is prepared according to the method of Nicole. Dmelcos vaccine has also been employed in this country as stated by Wise and Sulzberger¹ but its routine use has been impossible owing to the difficulty in obtaining it.

For some unaccountable reason, a satisfactory culture of Ducrey streptobacilli for preparation of a vaccine has not been successful in this country until quite recently. In this paper we give the results of our study with intradermal injections of Ducrey vaccines for the diagnosis of chancroid and compare the results of two American vaccines with Dmelcos vaccine.

One of the American vaccines was prepared by Greenblatt and Sanderson¹ at the University of Georgia. The other is a commercial preparation made by Lederle Laboratories

Ito,² working under the supervision of Bruck at the clinic of Neisser was the first to prepare a vaccine from cultures of Ducrey streptobacillus. He used it for diagnosis and treatment of chancroid. Reenstierna³, Frei,⁴ Nicole,⁵ and Rivalier⁶ corroborated his results. Frei⁴ obtained positive intradermal tests in cases of chancroid with pus from chancroidal buboes. The value of this test was confirmed by Bratzlavskij and Moreniz,⁷ and

Cole and Levin.⁸ In America, Teague and Deibert,⁹ Bram¹⁰ and Saelhof¹¹ have experimented with cultures of Ducrey streptobacilli. Recently Hunt,¹² Du laney,¹³ and Greenblatt and Sanderson¹⁴ have cultured the streptobacillus and prepared vaccines. The last mentioned authors compared the diagnostic value of their Ducrey vaccine with that of pus from chancroidal buboes and found the vaccine more satisfactory.

The test is performed on the flexor surface of the forearm with 0.1 cc of vaccine injected intradermally. To obtain uniform dosage, it is important to mix the vaccine by shaking before injecting. In cases of chancroid, an erythematous papule appears within twenty-four hours, occasionally on the second or third day. This is sometimes slightly tender. An erythematous areola, varying in size, may be present but usually disappears after two or three days. The test should be read on the third or fourth day but when positive may remain for weeks. A reaction of short duration has little or no value. The papule should be 8 mm or more in diameter. Papulovesicular, papulopustular, or nodular types of reaction may be present.

In controls, a small papule or area of erythema may develop during the first twenty-four hours but usually disappears on the second or third day.

For the proper interpretation of the Ito test, several points should be borne in mind. The test usually becomes positive during the first or second week after development of the infection, but sometimes not until the sixth week or later. It is incorrect, therefore, to speak of the

RESULTS OF THE ITO TEST WITH DMELCOS VACCINE

| | NO OF CASES | NO OF TESTS | CASES— POSITIVE REACTIONS | CASES— NEGATIVE REACTIONS | REMARKS |
|---|----------------|----------------|---------------------------------|---------------------------------|--|
| Chancroid | | | | | |
| With buboes | 22 | 22 | 22 | 0 | Nine cases gave negative tests throughout their stay in the hospital. One of these was tested 10 months later and still gave a negative reaction |
| Without buboes | 85 | 105 | 76 | 9 | |
| History of chancroid or bubo | 28 | 28 | 24 | 4 | Cases with negative Frei tests only were included |
| Cases with buboes and positive Frei tests | 27 | 27 | 6 | 21 | The six cases giving positive Ito tests were clinically mixed infections |
| Controls | | | | | |
| No history of chancroid or bubo | 117 | 140 | 3 | 114 | Three normal individuals gave positive Ito tests. One of these also gave similar reactions to Frei antigen (mouse brain) and normal mouse brain emulsion |

percentage of positive tests without specifying the duration of the infection. The test is practically always positive when chancroidal buboes are present. Once the test has become positive, it remains so throughout life but in several instances the test has become negative following intravenous injections of Ducrey vaccine for therapy.

We believe the test to be specially valuable in longstanding chancroids. In the majority of these phagedenic lesions where autoinoculations are usually negative, the Ito test is always positive. The negative autoinoculations in these cases is probably due to the overgrowth of the Ducrey streptobacillus by common pyogenic bacteria.

A study of our cases substantiates the opinions of other observers that the vaccine is satisfactory as a diagnostic test in the majority of cases as is shown in the above table.

The results of the comparison of the three vaccines are as follows:

Group 1 Comparison of Greenblatt's Vaccine with Dmelcos—One hundred and eighty tests were performed on 86 individuals. In 44 cases the tests were positive and in 46 cases negative to both vaccines. In 26 of the positive cases, the two vaccines gave equal reactions. Greenblatt's vaccine gave stronger reactions than Dmelcos in 4 cases and weaker reactions in 16 cases.

Group 2 Comparison of the American Commercial Vaccine with Dmelcos—Sixty-two tests were performed on 27 persons. Nineteen tests were negative and 12 positive with both vaccines. In 5

of the positive cases, the two vaccines gave equal reactions. The commercial vaccine was stronger in 1 case and weaker in 6 cases.

Group 3 Comparison of the Three Vaccines—Three hundred and sixty tests were performed on 112 persons. Seventy-six gave negative reactions to all vaccines. Forty-four cases gave positive reactions, of which 26 were of equal intensity, 8 gave the strongest reaction with Dmelcos, 4 with Greenblatt's, and 4 with the commercial vaccine.

When the reaction to Dmelcos vaccine was negative, the other two vaccines also gave negative reactions in all the cases. The differences in the positive reactions were slight and in no case of such a degree as to be of any practical value. Some of these may have been due to differences in the age of the vaccines.

Summary and Conclusions

In 107 cases of chancroid, 28 cases with a history of previous chancroidal infection, 27 cases with buboes and positive Frei test, and 117 controls, tests were made with 322 intradermal injections of Dmelcos vaccine, 210 of Greenblatt's vaccine, and 151 of an American commercial vaccine.

Attention is drawn to the fact that early cases of chancroid may give negative reactions for a few weeks. The reactions are practically always positive when buboes are present.

The test is of special value in longstanding chancroids where other diagnostic measures fail.

The two American Ducrey vaccines

gave reactions equal to those with Dmelcos vaccine. The tests with these vaccines confirm their specificity for diagnosis of chancroidal infections and are as useful as the accepted Dmelcos

Discussion

Dr David Bloom, *New York City*—It is gratifying to know that at last streptobacilli were successfully cultured and that a vaccine could be prepared in this country. Chancroid is an important venereal disease because of the frequently destructive form which it assumes and particularly because it is to be differentiated from syphilis and other important affections.

The investigations carried out by Dr Saunders and his collaborators are valuable and necessary for they show that the commercial vaccine and the vaccine prepared by Sanderson and Greenblatt of Georgia compare well with the French preparation called Dmelcos. This latter preparation we have been forced to use for many years in this country. In spite of the difficulties associated with the importation of this vaccine into the United States.

This intradermal test has been worked out in 1913 by Ito in Neisser's Clinic at Breslau under the direction of Bruck on a small number of patients. In 1923 Reenstierna at Pasteur's Institute in Paris continued this work and confirmed it on a much greater material. It is therefore also called the Ito-Reenstierna test. This test is recognized by all investigators as specific. It has proved its value for many years in differentiating chancroid from other diseases and particularly in investigations of lymphogranuloma venereum. About eight days after the infection this reaction becomes positive and increases in intensity with the duration of the chancroid. The presence of a

bubo favors an intense reaction. The following points have to be kept in mind when evaluating the test. The test becomes positive about eight to ten days after the infection, sometimes later. Some chancroid patients do not develop any positive skin reaction. This is however exceptional occurring according to Rivalier in one among two hundred patients. Certain non-chancroid patients may be hypersensitive to any foreign protein and react, therefore, to this intradermal test with erythema or a papule. But this simple protein reaction develops early a few hours after infection and disappears or diminishes in size within twenty four hours while the specific reaction in the chancroid patient appears late, develops to maximum size in forty-eight hours and persists for one to two weeks or longer. If in forty-eight hours there is no distinct papular reaction the test may be considered negative. One should also know that after intensive intravenous treatment with the vaccine the hypersensitivity of the skin may be changed manifesting itself by the earlier appearance of the skin reaction and its quicker disappearance. Of great importance is the fact that this intradermal test produces a positive reaction long after the infection has taken place. Frei has observed a positive test in a man twenty-eight years after infection and Reenstierna fifty years after infection. This fact diminishes the value of the test. For the positive test may also indicate past chancroidal infection and thus does not decide the nature of a lesion. In such cases the autoinoculation test is of immense value and the combination of both tests has been used at our wards in Bellevue Hospital with great benefit. The fear of some authors about the danger of persistence and extension of this inoculation chancroid seems to be without any grounds according to our experience.

While the clinical features of many cases of chancroid are fairly characteristic, we do not rely on clinical observation. For it may be a mixed chancre or may assume atypical form like the elevated nodular, milium, and serpiginous chancroid which require differentiation from syphilis, granuloma inguinale, and other diseases.

The direct microscopic examination of the stained material from chancroid is not as easy and practical as many writers make one believe. For even if the lesion is cleaned and material removed for examination from underneath the borders there are rarely streptobacilli in typical chain form present. They may therefore be confused with the contaminating bacteria, like staphylococci and gram negative bacilli (bacillus coli and bacillus pyocyaneus). According to Queyrat the Durey bacillus may also assume the

form of a coccus which makes it still more difficult to recognize. There are also present different gram positive germs which may be confused with the streptobacilli, like the enterococci which are identical with the streptobacilli urethras of Pfeiffer, and rods of the group of vibrioform bacilli found in balanitis circinata and ulcus gangrenosum. It is, therefore, necessary, when Ducrey bacilli are arranged in short chains, to use, besides the Pappenheim stain which is a fine double stain but not a differential stain, also the gram stain. For these obvious reasons we have discarded at Bellevue Hospital the method of examination by smear and rely only on the intradermal and autoinoculation tests.

Dr Helen O. Curth, *New York City*—I also want to report favorably on the use of the Ducrey vaccine (Lederle) in chancroidal infections. For years, in the Vanderbilt Clinic, New York, the Ito test was performed with the French Dmelcos vaccine alone and was satisfactory. Lately, the Ducrey antigen (Lederle) was also used. The two reactions were checked against each other. There was agreement between the two reactions not only in strength but also in character. The resulting erythema in positive tests in both instances was either without marked infiltration, or infiltrated or follicular or follicular-pustular. In one case blotchy redness resulted from either test. The reaction was considered doubtful. The resulting erythema in positive cases was per-

haps slightly larger in size with the Ducrey vaccine (Lederle) than with the Dmelcos vaccine. I want to mention that even a strongly positive Ito test is no proof that the present condition of the patient is chancroid.

In our opinion the American commercial Ducrey vaccine (Lederle) is fully able to replace the French vaccine which could be obtained only with great difficulties in this country.

Dr Orlando Canizares, *New York City*—I wish to thank Drs. Bloom and Curth for their discussions. I am glad that Dr. Curth's experience agrees with ours.

We believe that there are only two reliable diagnostic procedures in chancroidal infections—autoinoculation and Ito test. Both are used as a routine in Bellevue Hospital. The autoinoculation is not by any means dangerous. This procedure is of great value in early cases, when positive it is a definite proof of the chancroidal etiology of the lesion. However, if the autoinoculation obtained is small and dries up spontaneously it should be considered negative.

The Ito test is extremely useful, but its value in early stages is limited. Therefore, in the diagnosis of chancroid both procedures should always be used as their value depends upon the duration of the lesion.

POSTGRADUATE MEDICAL EDUCATION

A course on general medicine is being given this spring at the Auburn City Hospital, Auburn, N. Y., for the Cayuga County Medical Society. On March 2, Dr. Clayton W. Greene, of Buffalo, will lecture on Nephritis. Dr. Greene is Clinical Professor of Medicine, Buffalo University. On March 9, Dr. Will Cook Spain of New York City will lecture on Asthma. Dr. Spain is Physician, Post-Graduate Hospital. On March 16, Dr. Charles B. F. Gibbs, of Rochester will lecture on Diabetes Mellitus. Dr. Gibbs is Associate Professor of Medicine, Rochester University.

W P A X-RAY TO K O T B

A mass effort to curb tuberculosis among poverty-stricken families, through x-ray examinations of the 529,000 men, women, and children on home relief in New York City was announced recently by Mayor LaGuardia. No campaign of equal magnitude has ever been attempted in the past, the mayor told reporters after he watched four persons a minute pass before the x-ray machines at a W P A tuberculosis clinic. The records kept will be "unusually complete," the mayor said, and a full checkup will be made on families and friends of those found infected.

"SKIN" REMEDY IS REMEDIED

Ten cents a bottle was the cost of a marvelous ointment sold for one dollar by a quack just sent to the penitentiary as the result of an investigation by Dr. Harold Rypins, Secretary of the State Board of Medical Examiners. He did not claim it was an 'old Indian remedy' or

"a gypsy discovery," but merely touted and tooted it as a "secret ointment, discovered by monks in Ireland 700 years ago and inherited by him through his family in 1932."

Quite appropriately, it was a "skin remedy."

THERAPEUTIC USE OF BACTERIOPHAGES, PARTICULARLY IN SEPSIS

WARD J. MACNEAL, M D, New York

(From the Department of Pathology and Bacteriology New York Post Graduate Medical School and Hospital Columbia University)

SINCE the pioneer observations of transmissible bacteriolysis by Hankin, Twort, and d'Herelle and the recognition of the agent as a filterable virus by Twort, the further biologic studies have added much confirmatory evidence in favor of this view. The name bacteriophage was bestowed by d'Herelle and to him we owe a large part of our present knowledge of these viruses which attack, derange, and destroy bacteria. From the work of numerous investigators, the bacteriophage particles are known to range, in general, from 10 to 100 micro-mu in diameter. Borrel,¹ in 1928, succeeded in staining minute granules which had been set free by bacteriophage lysis. Schlesinger,² in 1933, was able to recognize the particles of coliphage in their native state by use of the dark field microscope and to determine their form and to count them in a satisfactory manner. By use of the centrifuge he was able to ascertain their size. He also has observed the agglutination of the particles by suitable antiserum. In a discussion of somewhat similar results in the centrifugation of herpes virus, Bechhold and Schlesinger³ say that the significance of their observations is the same as would be the demonstration by the microscope of uniformly alike bodies of a diameter of 0.2 micro-mu and their identification as the virus elements. In 1937, MacNeal Frisbee, and Krumwiede,⁴ employing a technic similar to that used by Castaneda for staining the virus bodies of typhus fever, were able to demonstrate differentially stained particles in the interior of bacterial cells undergoing lysis by bacteriophage, particles of such size as to conform to the measurements of bacteriophage

particles derived from filtration experiments. It seems, therefore, that the designation of 'invisible' cannot longer survive in the descriptions of the rickettsias, bacteriophages, or indeed of many other viruses in the filterable group. d'Herelle early recognized a distinction between the bacteriophage particle, the essential reproductive element, and its ferments or enzymes. The validity of the pioneer experiments on which this recognition was based has, on subsequent examination, seemed rather insecure. More recently, however, Sertic⁵ and his associates have found important new evidence, indicating quite clearly the existence of soluble, diffusible and non-reproductive enzymes elaborated by the relatively nondiffusible bacteriophage particles, which latter are endowed with the (vital) property of unlimited reproductivity. Gratia,⁶ by use of centrifuge of high velocity, has been able to concentrate the bacteriophage particles and Girard and Sertic,⁶ by using a centrifugal force of 300 000 G, were able to destroy a large part of the bacteriophage particles without reducing the concentration of the lysine. Stanley, Wyckoff and Northrop⁷ have applied chemical and physical methods to the study of viruses, including bacteriophage, and have been able to concentrate the virus proteins which possess the properties of enzymes. These authors seem not to distinguish between the living virus particles and the chemical enzymes produced by living cells, a distinction which interests the biologist. Studies in this field are obviously of great fundamental and theoretic interest.

Of greater practical importance, how-

FIG 1 Response of the blood of a healthy person to intravenous injection of 5 cc staphylococcus bacteriophage. The control normal leukocytes and normal pooled serum showed an activity against the bacterial suspension indicated by ingestion of 490 bacterial cells by 100 polynuclear leukocytes. The experimental subject, designated as P, had a blood serum which at the start was slightly below the control in opsonic effect, PS, 440 bacterial cells per 100 leukocytes. In 15 minutes after injection of bacteriophage this opsonic power was increased, giving 560 phagocytized bacteria and at one hour it was still higher, 620 bacteria, declining after that time. The activity of the phagocytic cells of the experimental subject is indicated by the line PC. This activity remained below the normal average for the first hour, but it was markedly elevated at the end of two hours and remained high at 24 hours. The behavior of the white cells, WBC, polynuclears neutrophilic leukocytes and of the eosinophiles is also indicated.

ever, are those studies which are concerned with the preparation of bacteriophages⁸ in such form that they may be safely used to combat infection in the body. Ordinary broth filtrates are useful for application to surface lesions, including those of the skin, intestine, and even of the urinary tract. For injection into the tissues and into the blood stream the bacteriophages are developed in a more bland medium in which the amino-acid asparagin is the only source of food nitrogen. Relatively large quantities of such preparations may be injected intravenously without untoward effects due to the medium itself, and we have gradually come to the exclusive use of these for injection into the tissues as well.

The early observations of d'Herelle suggested that bacteriophages aid in the treatment of bacterial infections by killing and dissolving the infectious microbes, and it still seems that such destruction actually takes place in the lumen of the intestine and of the urinary

tract. However, further studies have clearly shown that this mechanism is not effective in the presence of blood, blood serum, or purulent exudate and hence of no use in the interior of the body tissues. As early as 1925, Bazy⁹ employed the staphylococcus bacteriophage of Gratia in the treatment of all sorts of so-called pyogenic surgical conditions, sometimes by encircling the lesion with a series of injections and in other cases by subcutaneous injection at a distance. By either method, equally good results were obtained and the lesion progressed rapidly to healing. The mechanism of action was not in accord with the theory of d'Herelle. In fact, some lesions healed rapidly under bacteriophage treatment, while the staphylococci isolated from the lesion proved more or less resistant to the bacteriophage in the test-tube experiment. Occasionally the response to treatment with staphylococcus bacteriophage was favorable, although the infecting organism proved to be a streptococcus or some other germ. Bacterial extracts which did not contain bacteriophage and bacterial lysates obtained by various other procedures gave similar therapeutic results. Bazy concluded that, in the therapeutic use of staphylococcus bacteriophage, events proceed as if the lytic principle played no part at all and the curative effect were due essentially to the soluble products of the bacteria, stimulating hyperactive digestive function of the leukocytes. Subsequently, studies of many workers,¹⁰ some in our own laboratory, have now made it quite clear that the bacteriophage preparation exerts other effects besides that of bacteriolysis, and that some of these come into play in the circulating blood and in the tissues. The most immediate of these is an opsonic effect which can be demonstrated in the test tube in the presence of serum, in the experimental animal, and also in the blood of the human individual within fifteen minutes after use of bacteriophage.

One experiment, done in collaboration with Miss McRae, may serve to illustrate. In this instance blood was drawn

from the elbow vein of a healthy person for determination of opsonic and phagocytic index. A white and differential blood count was taken. Then an intravenous injection of 5 cc asparagin staphylococcus bacteriophage was given. After lapse of 5 minutes, another sample of blood was taken for determination of opsonic and phagocytic index, again at 15 minutes, at 60 minutes, and at 120 minutes after the injection. Blood counts were taken at 60 minutes and at 120 minutes. These examinations were repeated again at the end of 24 hours. In 15 minutes after the phage injection the opsonic activity of the serum was increased to 500 as compared with 440 at the start and it rose to 620 at 60 minutes, declining in the later examinations. These figures represent the absolute numbers of phagocytized cocci counted in 100 leukocytes on the microscopic preparations. The phagocytic index remained nearly at the same level for the first hour and was more than doubled at the end of the second hour and it remained almost as high at 24 hours. The total white cells and the polynuclear leukocytes showed minor alterations suggesting a mild temporary stimulation. Of greater interest, perhaps, was the behavior of the eosinophiles, which numbered 53 per cubic millimeter at the start, diminished to 28 at the hour, rose to 215 at two hours and 221 at 24 hours. We do not wish to ascribe too much importance to these observations until more experimental facts have been accumulated. However, it is interesting and somewhat suggestive to compare these observations on a healthy person with the somewhat similar studies on the septic patients mentioned farther along in this communication. Obviously the opsonic effect is much more prompt than any lytic effect and it could hardly be a reaction of immunity. There can be little or no doubt that it is due to enzymes in the bacteriophage preparation which immediately attack the respective bacteria and render them more susceptible to phagocytosis by the wandering leukocytes and by the fixed phagocytic cells of the reticulo-endothelial system.

After two hours the leukocytes themselves ordinarily become more actively phagocytic, apparently because they have taken up the bacteriophage particles and enzymes. Furthermore the experimental evidence indicates that such phagocytic cells are now able to destroy and digest the phagocytized bacteria more efficiently with the aid of the bacteriophage and its enzymes. Subsequently, as pointed out by Albee and Patterson¹¹ and later emphasized by the work of Hoder,¹² those bacteria which escape destruction are often altered in their character and especially in respect to their virulence by action of the bacteriophage, so that the severity of the infection is ameliorated. These properties of the bacteriophage preparation thus permit it to bring immediate help to the patient who is fighting against a bacterial infection threatening to overwhelm him. If the acute emergency is successfully met it must be evident that some degree of immunity, such as follows an unaided recovery from infection, may have been achieved by the natural resources of the patient.

The technical methods of applying bacteriophage are of some importance for success and there is need for still further improvement in this field. At present we rely chiefly upon intravenous injection of the bacteriophage in the asparagin medium. If there are readily accessible lesions, these are treated by application of the phage to the surface, by irrigation with phage, and by injection of it through a fine needle into the lymph spaces by multiple punctures encircling the lesion. We prefer to avoid all elaborate or possibly injurious instrumentation, particularly in the air passages, the intestine, and the urinary tract, relying upon the hematogenous route to bring the bacteriophage to internal lesions. When the bacteria are present in the circulating blood, the intravenous administration of bacteriophage is imperative and the patient should be spared all operative procedures and especially the administration of anesthetics, until the infection of the blood stream has been brought under control. This is emphatically true.

FIG 2 Condensed clinical record of L. T., white male, aged 15 years. Note absence of response to enormous doses of bacteriophage, a total of 210 cc on December 1 and 775 cc on December 2. This boy had large bacterial vegetations on the valves of the heart and embolic lesions in the brain.

in the invasive stage of hematogenous osteomyelitis¹³ but is also not to be forgotten when the supposed "focus of infection" is located elsewhere. In these septic conditions the intravenous injections are given at intervals of 45 minutes in gradually increasing amounts until the patient goes into a chill. In the typical reaction, the distressing rigor lasts from 5 to 50 minutes, during which the temperature usually rises to 104 to 108 degrees, sometimes higher. Following this the patient becomes rosy and there is profuse perspiration with fall in temperature during the next six to ten hours to a much lower level, sometimes below 99. One then continues smaller intravenous injections of the bacteriophage twice daily until the blood culture is negative, then once daily until recovery is complete and then twice a week for some months to forestall recidive. In staphylococcus bacteremia the initial dose of bacteriophage is ordinarily 0.5 to 2 cc. In bacteremia due to the colon bacillus, typhoid bacillus, or other related organisms the initial dose is 0.1 to 0.3 cc. If the shock reaction is not obtained the prognosis is not so favorable. One therefore persists in the serial injections in such cases until a total amount of 100 to 300 cc of bacteriophage has been administered. Failing to obtain a reaction in a patient with persistent positive blood culture, one tries again, after three or four days, with a second series of increasingly large doses. When the staphylococcemia persists, one suspects the presence of bac-

terial growth on the valves of the heart or in a thrombus in one or more of the larger veins. The intravenous injection of neoarsphenamine appears to supplement the action of bacteriophage in such instances. In streptococcus infection, on the other hand, one places chief reliance on sulfanilamide and antistreptococcus serum and employs the streptococcus bacteriophage, when found potent by laboratory tests, to supplement these agents.

Our experience in bacteriologic study and preparation of bacteriophage for treatment of septicemia has now extended to more than 300 patients. In some instances these patients have been seen in consultation and in a few instances we have carried out the bacteriophage treatment ourselves. Consideration of the summarized records of a few of these may help to illustrate the actual methods employed in treatment.

L. T., white male, aged 15, born October 4, 1922, gave history of rheumatic fever with severe cardiac difficulty at the age of 5 years. Since then he had developed into a vigorous athletic boy. On Wednesday, November 24, 1937, while engaged in a strenuous hockey game, he suffered a slight abrasion of the left ankle, which received little or no attention. On Friday, November 26, he developed a severe head cold with fever, headache, vomiting, and epistaxis. On the next day he complained of blurred vision and double vision. The physician who had cared for him as a child was called and a trained nurse was placed on duty on Sunday. Twitching of left side of the face was noted on this day. He was transferred to the hospital on Monday, November 30, with admission temperature 103 F, pulse 116, respirations 26, at which time general hyperesthesia, slight general cyanosis, twitching of left side of face, slight irregularity of pupils and sluggish reaction to light, and a blowing systolic murmur at the heart apex were noted. A diagnosis of acute nasal sinusitis with possible encephalitis and possible septicemia was recorded. A blood count taken at 7:40 P. M. showed a

leukocytosis of 9,500 with 87 per cent (8,265) polynuclears. A blood culture taken at the same time showed positive growth of staphylococcus at 11 30 A.M., December 1, and subsequently there developed on the plates colonies of *Staphylococcus aureus* too numerous to be counted, but estimated at more than 1,000 per cc of blood.

At the request of the attending physician we undertook bacteriophage treatment at once. A specimen of blood was taken at 11 31 A.M., December 1, for blood culture, opsonic index, and phagocytic index. Then an intravenous injection of 2 cc. stock asparagin staphylococcus bacteriophage was given, followed at intervals of approximately 45 minutes by intravenous injections of 4-6-8-10-15-20-25-30-40 and 50 cc., the last injection at 7 26 P.M. The total amount of phagocytic was 210 cc. There was no reaction. The opsonic index showed little, if any, change. The condition was recognized as desperate. On the next morning a second series of intravenous phage injections was begun with 25 cc. at 8 A.M., followed at fairly regular intervals by progressively larger doses up to 75 cc until a total amount of 775 cc had been given by 5 20 P.M. There was no reaction. The patient continued in a state of low delirium from which he could be aroused to rational response by moderate effort. During the night he sank into a coma and could not be aroused after 2 30 A.M. Respirations ceased at 8 10 A.M., December 3. Blood films taken at 9 40 A.M., December 2, showed phagocytized diplococci within the polynuclear leukocytes of the circulating blood.

Necropsy at 10 15 A.M. revealed large friable, blood stained vegetations on the mitral and aortic valves and, behind the posterior leaflet of the tricuspid valve a firmly attached, ragged, grayish yellow vegetation, measuring $10 \times 5 \times 2$ mm. The stained sections showed massive collections of Gram positive cocci in the superficial layers of these vegetations. The kidneys contained multiple small pyemic abscesses and there was a large infarct of the spleen. Within the skull

FIG 3 Condensed clinical record of G S white male aged 8 with persistent staphylococcus bacteremia osteomyelitis of left tibia and clinical signs of cardiac involvement. On January 11 at the time of the sharp reaction to bacteriophage, there was a marked decrease in the circulating leukocytes. Low phagocytic index persisted until the blood culture became negative. The opsonic index remained high after the reaction on January 11. Neoarsphenamine was used as an adjunct to the bacteriophage therapy.

there was a sub-dural clot over the left fronto-parietal region, measuring $80 \times 100 \times 10$ mm, apparently originating from a ruptured pial vessel weakened by mycotic aneurysm. Another hemorrhage was found, apparently originating in the left occipital lobe, infiltrating the brain substance and rupturing into the sub-arachnoid space and into the posterior cornu of the lateral ventricle to fill the ventricles with blood.

G S white male, aged 8, born March 31 1920 kicked himself on the left ankle with roller skate about December 27, 1937, producing a small abrasion. On Thursday January 6 he turned his ankle while skating but gave the injury no particular attention until Saturday, January 8, when the entire left leg became painful and his temperature rose to 105 F. He vomited several times. He was seen by a physician on Sunday and was admitted to the hospital at 3 20 P.M. on Monday, January 10, 1938, with diagnosis of cellulitis of left calf and in

fect abrasion of ankle. Roentgenologic examination revealed soft-tissue thickening in the lower third of the left leg without gross osseous or articular abnormality. Blood culture was taken at 1 A M, January 11. At 7 30 A M the boy complained of pain in right upper arm and in left leg. At 11 32 on this day, incision of the left leg revealed a thickened periosteum. This was incised and drill holes were made into the lower anteromedial aspect of the tibia above the epiphyseal line. Microscopic examination of the hemorrhagic exudate from the surgical wound revealed an occasional clump of cocci and the cultures subsequently gave abundant growth of *Staphylococcus aureus*. Meanwhile the blood culture taken at 1 A M showed many small colonies and a tentative diagnosis of staphylococcus bacteremia was communicated to the attending surgeon at 4 50 P M, who at once requested bacteriophage therapy, which was administered by our own group.

A blood count was taken at 5 03 P M. and another blood culture at 5 04 P M. Then at 5 05 an intravenous injection of 2 cc stock asparagin staphylococcus bacteriophage was given, followed by similar injections of 3-5-7 and 10 cc at approximate intervals of 40 minutes, the last injection at 7 47 P M. At 8 20 P M the chill began, at which time his temperature was 102 and pulse rate 132. It lasted 18 minutes and was only moderately severe. At the end of the chill, 8 38 P M, the rectal temperature was 104.6 F. The patient vomited about 300 cc at 8 41 P M. Blood for opsonic and phagocytic study was obtained at the start of the phage injections, at the beginning of the chill, 8 24 P M, and again at 8 45 P M after the termination of the chill. The blood count was taken again at 9 03 P M about half an hour after the chill had ceased. These laboratory examinations were repeated the next morning, January 12, at 8 10 A M.

The behavior of the blood count, the opsonic index, and the phagocytic index in relation to the chill reaction and the reduction of bacteria in the blood is of peculiar interest. Before the phage in-

jections were started the white blood cells were 10,050 and the polynuclears 8,894, the opsonic index was 1.8 and the phagocytic index 0.6. Four minutes after start of the chill the opsonic index was 2.1 and the phagocytic index 1.6. At 8 45 P M, seven minutes after the chill terminated, the opsonic index had dropped to 1.1 and the phagocytic index to 0.8. Even more remarkable was the drop in white blood cells. The count at 9 03 P M, 25 minutes after termination of the chill, was 1,550 white cells per cubic millimeter and 992 polynuclear leukocytes. From our earlier studies of the internal organs of rabbits injected intravenously with staphylococci and bacteriophage it is not difficult to visualize the phagocytosis of bacteria and of injured leukocytes which was taking place in the endothelial cells of this boy's spleen, liver, lymph nodes, and bone marrow between 5 P M and 9 P M on this day.

The patient was distinctly improved after this, but his condition was far from satisfactory. At 8 05 A M, January 12, his blood pressure was 110 systolic and 40 diastolic. The heart apex beat was visible well out beyond the nipple line and the first sound was muffled. The liver margin gradually extended below the costal margin and became tender and on January 14 it was continuously painful. The cardiac dilatation may have been temporarily aggravated by the transfusion on January 13, although this was very carefully given by the fractional method to safeguard the weak heart. Perhaps the most ominous sign was the persistence of a small number of staphylococci in the circulating blood. By January 17 the circulation was improved, the heart apex was palpable about 5 mm mesial to the nipple line in the fifth intercostal space. The liver margin was still below the costal margin. On January 21, because of apprehension in regard to the mitral valve, we gave him 0.2 gram of neoarsphenamine intravenously and this was followed by 0.3 gram on January 25 and 29. As shown at the bottom of the chart he received intravenous bacterio-

phage twice daily and a larger series of doses on January 14, 15, 18, 20, and 24. These more heroic doses produced no evident reactions, which behavior tended to increase our concern about the cardiac valves. The opsonic index assumed and maintained a high level but the phagocytic index remained consistently below 0.5 until the blood culture became negative. This seems to be in accord with theoretical expectation because active phagocytes would tend to be used up in the presence of opsonized bacteria. The phagocytic index rose to 1.3 on January 24, when the blood culture first became negative and was 1.6 on January 31. The blood culture on January 26 again became positive, showing one colony per 4 cc. of blood and after that it was not again found positive. The upset on February 9 and 10 caused some alarm but it was apparently due to a dietary indiscretion. The patient was discharged on March 19, 1938. He is walking without crutch or cane and there remains only a small crust on the tibial wound. Intravenous bacteriophage is being continued three times per week.

Our series of patients with infection of the urinary tract with colon bacilli is also large but the cases of colon bacillus infection of the blood stream are rather few, probably less than 25 in our series. An example of each may serve for illustration.

C. A., white female, aged 31, had been ailing for some time and on August 26, 1935, she was admitted to hospital on account of fever and irritation of the urinary tract. Blood culture taken at 4 P.M., August 26, gave positive growth of colon bacilli. After a chill her temperature reached 105 F at 8 P.M. On August 27 cystoscopic examination added no important information. Upon recognition of the growth in the blood culture on this day a grave prognosis was given. On August 28 culture of the urine yielded 12 billion colonies of colon bacilli per cubic centimeter of urine. It was decided to try bacteriophage therapy. Two intravenous injections were given, 0.2 cc. at 3:30 P.M. and 0.3 cc. at 4:15

FIG. 4. Condensed clinical record of C. A., white female aged 31 with pycelonphritis and colonbacillus bacteremia. Intravenous injection of coli bacteriophage on August 28, was followed by a definite reaction with chill and temperature rise to 108 F. With continuation of the intravenous phage therapy there was rapid progress to clinical recovery and complete sterilization of the urinary tract.

P.M. About half an hour later, the patient developed a chill and her temperature rose to 108 F at 6 P.M. and then declined rapidly to 97 F at 12:30 mid night. This appears to have been a fairly typical severe bacteriophage reaction. On August 29 an intravenous injection of 0.1 cc bacteriophage was given at 10:40 A.M. and a second intravenous injection of 0.15 cc at 3 P.M. There was a slight chill after each of these injections and the temperature rose to 105.4 F at 4 P.M. On August 30 a blood culture was taken early in the morning and this culture remained sterile. On this day an intravenous injection of 0.15 cc bacteriophage was given in the morning and again in the afternoon without reaction and on August 31 the same treatment caused no reaction. On September 1 the intravenous dose was increased to 0.2 cc. twice a day and this was continued through September 3. The patient improved rapidly and was discharged from hospital on September 4. It is of interest that the urine specimens obtained on September 2 and September 4 contained bacteriophage, illustrating the well known ready passage through the kidney of bacteriophage injected intravenously. On September 18 a specimen of urine was found to be free from bacteria and bacteriophage. The patient appeared entirely well.

M. G., white female aged 36 had an attack of "grippe" about March 14, 1936, which was accompanied by some dysuria

FIG 5 Condensed clinical record of M G, white female, aged 36, with pyelonephritis and signs of peri-nephritic abscess. Enormous numbers of colon bacilli were present in the urine on March 24. Intravenous injection of 0.2 cc of the asparagin preparation of coli bacteriophage on March 26, was followed by a mild chill and temperature rise to only 103.6 F. The intravenous injections of bacteriophage were continued. Clinical improvement was almost immediate and the urinary tract was bacteria-free on April 20.

and frequency. She recovered promptly and was free from symptoms until March 21, when she became aware of a dull pain in the right flank radiating toward the pubes. On March 23 she had a severe chill and her temperature rose to 103.6 F, with renewal of urinary frequency and dysuria. There was a normal menstrual period March 14. Physical examination was essentially negative except for marked tenderness and spasticity in right flank and over the right kidney anteriorly. Roentgenologic examination on March 24 showed enlargement of the right kidney with inconclusive suggestion of peri-nephritic abscess. The urologic consultant, on March 25, advised conservative treatment by intravenous injection of mercurochrome, production of a ketosis, or, preferably, in his opinion, the intravenous injection of bacteriophage, if the urine culture should reveal the presence of colon bacilli. Fortunately, a specimen of urine for bacteriologic study had been taken on March 24, and the cultures of this yielded colon bacilli, approximately 17 billion colonies per cc of urine.

On March 26, at 11:37 A.M., a specimen of blood was taken for culture. This gave a negative result. Then at 11:40 A.M. an intravenous injection of 2 cc of 1:10 dilution stock asparagin coliphage was given. At 12:40 P.M. the patient went into a chill, with chattering of teeth and moderate cyanosis. The

chill lasted 20 minutes and the temperature at its termination was 103.8 F. It was followed by profuse perspiration. At 4:52 P.M. a smaller intravenous injection, 0.5 cc of 1:10 dilution, of the same bacteriophage was given. Subsequently the phage injections were continued twice daily. The patient improved almost at once and was discharged from the hospital on April 3, 1936. The urine specimen of the previous day still contained colon bacilli, yielding 2,160 colonies per cc on culture. Another urine specimen obtained on April 20 was found free from bacteria.

Summary

1 Bacteriophages are evidently viruses which cause derangement and destruction of certain bacteria. The exact nature of these viruses is still debated but it now seems almost certain that a bacteriophage is a minute particle of living matter capable, among other functions, of producing potent enzymes.

2 It is possible to make preparations of bacteriophages which are suitable for injection into the tissues and into the blood stream. A protein-free asparagin medium has been found useful for this purpose.

3 Bacteriophages may dissolve bacteria in the urine or within the lumen of the intestine but they appear unable to bring about such direct solution of bacteria in the blood or in exudates. In these latter situations, the bacteriophage preparations exert a pronounced and almost immediate opsonic effect and subsequently play a part in aiding the phagocytic cells to ingest and destroy the bacteria. Bacteria which escape destruction may also undergo alteration in character and partial loss of virulence as a result of bacteriophage action.

4 The technic of bacteriophage therapy is of some importance for success.

5 Summarized clinical records of severe infections with staphylococcus and with colon bacillus have been presented as examples of bacteriophage therapy.

Discussion

Dr Morris L. Raskiten, Brooklyn—Dr MacNeal and his associates have been investigating certain phases of bacteriophagy for the past several years. Out of their studies have appeared results that have proved of practical value in the therapeutic use of bacteriophages. The inhibitory power of pus and whole blood on certain phages was reported from his laboratory in 1931. More recently he has made some interesting observations on what may be termed the indirect action of phages, that is the increased

susceptibility of bacteria to white blood cells in the presence of phage. He has also had an unusually large experience with severe cases of infection in which he has administered bacteriophage. Undoubtedly many in this audience are familiar with some of the reports that have appeared under his name. Our interest in bacteriophage—covering a period of some ten years—has been away from the clinical application being concerned chiefly with the biologic aspects. However no one can have any considerable experience with phages without being called upon from time to time for phages to be used therapeutically.

Bacteriophagy in the test tube is a relatively simple and clear-cut phenomenon. In a medium containing actively growing susceptible culture the addition of unbelievably small amounts of active phage results over a variable period of time in the complete dissolution of the culture. Under these highly artificial conditions, with the odds in favor of the lytic agent. It is little wonder that for many years a good deal of energy has been spent in attempting to reproduce these conditions in vivo. And when there has been failure, a large outcry has been raised regarding the inefficacy of bacteriophage in the treatment of infections. In vivo conditions are much more complex than the simple broth test tube, and with conditions now favoring the growth of the bacteria the task of destroying them by any means is a very difficult one.

Many bacteriophages may be able to effect complete lysis of a bacteria in the test tube and prove to be absolutely worthless as a therapeutic agent. Most races of staphylococcus phages will lyse hemolytic strains of staphylococci in vitro but there are only a very few races of staphy phages that can bring about lysis of staphylococci in the presence of serum or pus. However if one adapts a staphylococcus phage to increasing concentrations of pus and serum one can finally produce a phage that will dissolve susceptible culture in concentrations of pus and serum that inhibit nonadapted phages. Such a phage may now be regarded as a virulent phage. d'Herelle, in all of his studies dealing with the therapeutic application has insisted on using only those phages of maximum virulence. In many instances he has used phages that have been isolated from convalescent cases such phages have actually demonstrated their ability to act in diseased tissue. It is highly important to remember that not all phages are equally good. Care in the selection of highly active races of phages their further development and maintenance, for possible therapeutic application, is a fair-sized job in itself. Laboratories in which

investigative work with phages is being carried out, generally have on hand such selected races

If phage is to be used therapeutically care must be taken by the individual administering it to attempt as best he can to get the phage in as close contact with the infected tissue as possible. That means removing tissue debris, irrigating sinus tracts with saline thoroughly to remove the accumulated exudate and so forth. If one neglects these points one is likely to have the phage (staphylococcus phages particularly) inactivated before it reaches the seat of infection. With regard to the amount of phage to use there are no standard doses to go by. Our practice, following d'Herelle, has been to use larger doses of phage initially than those described by Dr. MacNeal. In cases of sepsis our initial dose is usually not less than 10 cc. diluted in 50-100 cc. of physiologic saline, given intravenously and very slowly. If no reaction occurs in three hours this dose is repeated. Failure to get a reaction after three injections, in our experience, always resulted in failure with that phage. Indeed it is difficult for us to understand why repeated intravenous injections of phage over a long period of time should ever be used. Since phage is antigenic, antibody against the phage develops after 5-6 days when it is given parenterally, and when antibodies are present (antiphagic antibody) the phage is neutralized very rapidly, when it is injected. The only method of circumventing this antiphagic action of the serum is to use a phage that is antigenically different from the one responsible for the production of the antiphage. But for all practical purposes intravenous phage

therapy in order to be effective should show a good result early in the treatment.

One of the reasons for some of the failures charged to bacteriophage, and only because phage was given, is that too often it is the last material used. My own experience in cases of staphylococcus sepsis has been with cases that have been on the wards for many days, and only when multiple transfusions and other therapeutic measures have failed bacteriophage is tried. By this time the spleen, kidneys, and heart muscle may be riddled with miliary abscesses, and even if the blood stream could be freed of organisms, enough damage to vital organs has occurred to bring about the death of the patient. I am certain that Dr. MacNeal's experience parallels mine in this respect.

Finally, in chronic cases of infection that are to be treated with bacteriophage, the physician should understand that he is dealing with living agents, the bacteria, and the phage, that as the organism attempts to and often is successful in adapting itself to a phage, it is necessary to re-isolate another phage to take care of the changing organism. All of which means a good deal of co-operation and understanding between the physician and the laboratory. Bacteriophage has value in the treatment of infections. Its effectiveness is directly proportional to the quality of the phage, the time when it is utilized, and the experience of the one who is to administer it.

The presentation of Dr. MacNeal has pointed out certain valuable criteria for determining the effectiveness of phage when it is to be used therapeutically. More studies along these lines will be very helpful.

"ONE IN TEN"—PROPHECY, NOT FACT

One person out of every hundred in the United States is infected with syphilis and nine more out of every hundred will acquire syphilis at some time in life if present rates prevail, Miss Lida J. Usilton, Senior Statistician of the United States Public Health Service, declared on January 18 at a meeting of the New York Chapter of the American Statistical Association at the Hotel Woodstock, in New York City. In discussing

the subject, "Do 10 in 100 Have Syphilis?" Miss Usilton stated "The estimate on the number who have acquired syphilis is 1 in 100.

The estimate on the number who under existing detection and treatment facilities will acquire syphilis at some time in life is 10 in 100. This has been aptly expressed as 'syphilis strikes one out of every ten adults'."

Following the report of a recent death of an infant from lead poisoning traced to the use, by the child's mother, of a lead nipple-shield, the Public Health Council has adopted an amend-

ment to the State Sanitary Code which prohibits the sale or use of such shields, according to an announcement by Dr. Edward S. Godfrey, Jr., State Commissioner of Health.

Preventive Medicine

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M D, DR.P.H, New York City

Editorial Note Under this title will appear short summaries of 'transition cases' from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies but will accentuate situations from the point of view of individual mental hygiene such as crop up in the everyday practice of medicine

Psychosis and Marital Troubles

THERE are happy, unhappy, and in different marriages. The ideal marriage, which is rather the exception than the rule, is the one in which the participants are well adjusted to one another and where they are real partners, companions, friends. If a man and a woman associate without caring much for one another, but at least are not enemies and show no active hatred toward each other, they can live together indefinitely if they are at least sexually adjusted. When however, there is no sexual compatibility or enjoyment, the marriage will eventually be destroyed or is practically disrupted even if life continues under the same roof, though there may be complete agreement or community of ideas in many respects.

..Marriage, in one form or another, is purely human. It demands in theory an adaptation that in practice is feasible under certain conditions only and it provokes an infinite kaleidoscope of conflicts and therefore of direct and indirect causes of mental difficulties leading to mental disorders, in certain minds more than in others. Religion, social and economic conditions, the partners' upbringing, their heredity, their original mental state, complicate the situation to a high degree and make married life even more absurd. Sometimes it is to be wondered at that there still are so many human minds which, in spite of badly

unadjusted marriages, have escaped in sanity

And yet, in their purified and highly civilized as well as in their simplest forms, wherever concessions are instinctively or deliberately made, both sexual life and marriage could be and sometimes are the most beautiful things in our existence.

There are all sorts of married relationships, but some are more typical than others.

Usually man dominates or leads and woman follows. This may be truly so or in appearance only. Whoever is the dominating partner does not matter if the other accepts the situation. Trouble brews when both are equal in strength and ambition and neither can endure the yoke of the other. The best arrangement, the greatest harmony results when they both find and keep their places, knowing their respective ability and value, leading in those matters in which he or she is superior and yielding in those in which she or he is inferior. That is true adjustment.

We see the submissive, weak willed male tugged along by the energetic, despotic female, who talks for him, decides for him, acts for him, protects him, much like the mother spider, except that she does not chew him up. Or the forceful male who never admits that the wife knows anything, who bullies and intimidates her and to whom she admiringly looks up for wisdom and guidance. In

(Excerpts from a lecture delivered on November 2 1938 before the East Flatbush Medical Society Brooklyn New York)

the extreme cases or among very ignorant people she is not only respectful and obedient but does not mind being physically mishandled. She anticipates blows from him and concedes, like in antiquity, his right to do anything he desires with her. She may adopt the attitude of the wife in one of Molière's comedies where she resents being defended against her husband by anyone. "*Et je veux qu'il me batte*." In one case he may need such a wife, in the other just such a husband is necessary to her.

A highly cultured, impetuous American married and divorced four wives because he was arrogant to all of them and mistreated them all and none of them stood for his fanciful caprices and brutality. As far as is known they did not remarry, were acquainted between themselves and Mrs. X Number One, the oldest in line, met on the most friendly terms. Mrs. X Number Two, Three, and Four. But X, now on the shady side of fifty, took to himself a very young and splendid-looking girl, with whom he lived in peace, "because there was no wedlock," as he explained. While he had no children with the legitimate wives, his mistress became a mother, he esteemed her highly all around and treated her with respect. He was even somewhat afraid of her, because as he said, "she had no obligations toward him, she was giving herself freely and willingly." No mental disturbance resulted either for him or for any of the five numbers—for several years, at least, as far as is known. But there was enough tinder to set a fire blazing, there were enough conflicts to cause mental trouble in less resistant minds.

A fine symbiosis was present between a merchant whose life consisted of attending to his store until late in the evening, lying down comfortably, going to sleep before finishing his paper and not minding and not questioning what his wife was doing. She, grateful for her freedom, used it out to the full, by going away when he was nicely tucked in and coming home and slipping quietly into the bed before he awoke. She made a

good housewife, attended to his needs as carefully as the best and permitted him even the sex relations when he desired it, about once a month. Never a hitch in this perfect idyllic adaptation and never any mental disorder of any sort. But possibilities for mental conflicts existed and mental disorder would have been rife if latent causes had been present in this couple.

The situation was different in the case of a chemist who was always aware of his importance—nay, greatness—and never lost a chance to arrogantly show it to his wife, either in the form of didactic instruction or in ordering her to do as she was told without protest or whumper. It so happened, however, that she too thought she was or could be something. Each time she made an attempt to manifest her individuality, to do something original and entirely apart from his field, he fatherly came upon the scene, occupied it all and began his "teaching" even where he knew nothing. Result the woman, tired of fighting, broke down mentally and the marriage went on the rocks.

One political leader lived for thirty years with his wife. They had a daughter. I knew them fairly well and I felt that there was something the matter with their marriage, without guessing just what. In the presence of strangers they were nice to one another. But the war between them—albeit silent—broke out late in life and then I learned about the trouble. The woman was entirely opposed to having sex intercourse with him—"with any one," she said, and their relations occurred very rarely and, on her side, reluctantly. She was not a homosexual. She was asexual, although anatomically, as far as could be ascertained, normally built. She told him repeatedly to look for another woman. She would have had no objection to his having one more apartment for that purpose. There had been no quarrels. She claimed to have nothing but friendship for him. But he could not think of another woman and finally he became mentally sick.

A man of fifty whose wife, much older, had deceived him successfully from the beginning as to her age. He had been happy with her. She always mothered him. He was her creation, her toy. Although the sex life she gave him was never exciting, that did not matter, as he did not know any better. But as soon as she stopped receiving him at all he made a discovery: "what sex relations really meant." He discovered this in the arms of a much younger female who seemed to be versed in all the devices and artifices of the trade. There was zest and enthusiasm. He became cold to his wife—indeed, he resented her having kept him in too great decency and having denied to him the Elysian delights. She was the one to collapse mentally. It was interesting to watch, not only her psychic change, but her physical metamorphosis as well. She had had a well formed body and, long ago, an attractive face. Her smile had been her forte. Her poise had enmeshed her partner more than any thing else. Her facial adaptation to a previous age, for the last twenty years, was her own special secret—a studied work of art. But now it could be seen how superficial it was after all and how transparent the disguise. Unhappiness tore down the mask—and her wrinkles were there. Her cheeks were sucked in and her lips pouted out, and a fine tremulousness of her fingers betrayed her age more than other symptoms. Remember Goya's caricature? But she cured herself quickly. She did not want her husband to leave entirely. So she gave one leap, made a somersault, and was her old self again. Her face became cheerful as before and she assumed her previous patronizing attitude toward him. Without a word she made him understand that she approved of his departure and that she was willing to let him take elsewhere what she could not give him. He was thankful, interpreting her behavior as devotion derived from real love.

A woman complained of various incoherent symptoms which, upon thorough investigation, were found to be due to lack of sexual satisfaction. Intercourse was

gratifying, but it occurred at very rare intervals. She had been treated for all sorts of nonexistent illnesses and finally, when a neurologist correctly diagnosed *hysteria*, the work stopped there. As no ailment can be treated with a mere diagnosis, this patient went from bad to worse. She suffered more because she *expected* frequent intercourse than because she needed it—more because she felt neglected than because she desired the contact so often. Her husband, when confronted with her, was astonished. He never suspected that *he* could be the cause of her suffering. Then he showed how impossible it was for him to act otherwise. Ever since he had his new job, he said, he left very early in the morning, worked hard a long day, came home exhausted in the evening, and promptly went to bed and to sleep. On Sundays he was still tired from the entire week. This explanation started the cure which made rapid progress until the patient was almost normal.

Among the many practical things which can find no place here but which can keep people away from serious pitfalls, I wish to emphasize the following few facts that may have their share in preventing mental maladjustment.

Mostly an interval of a few days between one intercourse and the next is advisable. Not merely for the sake of health is it necessary to avoid too frequent intercourse, but also for the purpose that the intercourse itself be more passionate and more satisfactory for both participants.

Even the most normal person may need a temporary, more or less protracted, rest from intercourse. This should not be interpreted as impotence. On the contrary, its natural aim is to prevent impotence, by rest, by shunning excess, and coitus during fatigue or exhaustion.

The necessity for rest may arise from actual excess or sufficiency of the intercourse itself, the desire of a temporary mental dissociation from one's partner, an existing transient unfriendliness or enmity between partners, or, finally, concentration in another direction, as

for the purpose of social activity, study, invention, writing literature or poetry

Of course, such a cessation of sex intercourse, while necessary to one partner, may be disagreeable to the other. Or there may be a misunderstanding, the other partner, or even the one principally involved, believing that the condition is permanent. Therefore, a frank, intelligent talk on the question between the partners may be of great help. If not, very unpleasant and sometimes unalterable, disastrous, results may follow.

But, as already previously implied, not only do unadjusted marriages provoke conflicts that lead to mental disorders or awaken dormant or potential tendencies to mental trouble, the reverse is also true. Psychopathic individuals in married life may cause its disruption, a cause which is so self-evident that it needs no further emphasis.

Or we see cases where both situations may coexist and destroy a marriage as well as a mind. One example will suffice to illustrate this state of affairs.

He is a recognized and professional writer. She—an amateur and unknown would-be or real composer, always haunted by paranoid thoughts—has never succeeded in having anybody but herself play her compositions. When she does so in the presence of others, some of her friends have a meaningful smile and, when pressed to offer an opinion, say, "Cute." It is true that she has been constantly and energetically—perhaps cruelly—discouraged by her husband. He is always telling her that she is wasting her time, that she has no talent at all, and

that she is making a fool of herself. He often forbids her to touch the piano and relegates her to the kitchen. Gradually, and after her hopes to get a public hearing have waned, she develops her pre-existing mental abnormality into a full psychosis. "Her husband, who is applauded in the press, well rewarded by publishers of books and periodicals, and adulated by admirers, is jealous of her greatness. He is afraid that if she becomes famous, she might obscure him by overshadowing." From this to the belief that "he has other women, that he is using some poison to get rid of her or at least to make her insane and commit her to an asylum," there is but one step. Inner voices begin to confirm this conviction and she wavers between killing her partner or committing suicide. Could this illness have been prevented? While her innate trends were incurable they might have never extended very far if this patient's husband had treated her in a more sympathetic and encouraging manner. Why not praise anybody who is making a sincere effort? Why not allow anybody to unfold any capacity?

I have seen somewhere a statement to the effect that it is better to fail in everything else and to succeed in home life than to succeed in everything else and fail in home life. This may be exaggerated, but it contains much truth. I would rather put it this way: inability to make marital life a success, where it is due to neglect or ignorance and not to disease or to social conditions, is at least as important a failure as any other great failure in life.

207 West 106th Street

BEAUTY ON THE BUDGET

The following bit of sarcasm appeared in Claude Callan's column, "Folks and Foibles," in a recent issue of the *Kansas City Times*.

"Why can't we have government beauty parlors furnished equally to all women? The government is planning to take charge of the health of the whole people, and surely no woman considers health as important as beauty. Under the present system of private ownership of

beauty parlors and private manufacture of beauty sauces, some women are able to buy all the beauty on the market, while some must be satisfied with soap and water on their faces. As a result some are always in the happy disposition of being beautiful enough to break up homes, while others are in danger of having their homes broken up. Let the government take over beauty and dispense it with a lavish and impartial hand."

Public Health Notes

J ROSSLYN EARP, L R C P, Dr P H
New York State Department of Health

Report for 1938

It is usually well into the second half of the year before our annual report for the preceding year can be printed. The Commissioner of Health is, however, required by law to submit annually on or before the first of March a report to the Governor which shall set forth the action of the department and other useful information. This typewritten brief contains several noteworthy items.

In the field of sanitation, Mr C. A. Holmquist reports that work has been commenced in 52 new sewage treatment works while 10 such projects were completed during the year. When the new works are in operation 78.4 per cent of our upstate population will have their sewage properly treated. This is more than double the population that was so served only ten years ago. Another year has passed without any outbreak of typhoid fever being traced to a public water supply. The state has been clean in this respect for ten successive years. The milk supply is not yet so safe. An outbreak of typhoid fever at Esperance resulted in a local ordinance requiring the pasteurization of all milk and cream to be sold or offered for sale.

The Tuberculosis Division reports a decline in the tuberculosis death rate from 42 per 100,000 in 1937 to 39 in 1938. They make the following recommendations for more complete control of this disease:

- 1 Some form of financial assistance to families in which there is tuberculosis. Poverty fosters disease both by reducing the budget for food and by the worry which it promotes in the whole family.

- 2 Progressive case finding by means of x ray examination of the adult population, especially persons between the ages of twenty and forty. It is in these age

groups that tuberculosis is still the leading cause of death, being responsible for more deaths than heart disease and pneumonia combined.

- 3 Liberalization of the policy governing payment for hospitalization. The pauperization of families resulting from the method of payment adopted in some localities at the present time for hospital treatment of persons who need such care and who are segregated for the protection of others, is a menace to public health and is poor economic practice.

- 4 Provision for the re absorption into industry of patients who have recovered. More complete rehabilitation and more suitable working opportunities and conditions should be made available.

- 5 More intensive public health education. This is vitally needed if superstition and ignorance are to be replaced by an intelligent public attitude toward the prevention and curability of the disease.

- 6 More public health nurses. Additional personnel of this type is essential in the prevention and control of tuberculosis in the home.

- 7 Extension of research to include all administrative and scientific phases of the tuberculosis problem. Economies cannot be realized in the future unless further knowledge of the factors influencing the disease is made available.

Pneumonia cases and deaths both decreased markedly, and a consideration of the case fatality rates indicates that the reporting of pneumonia has improved and perhaps also that treatment has been more successful. The program of professional education carried out in co-operation with the State Medical Society has been continued. One hundred and thirteen meetings have been held, at

which there was a total attendance of 1,958 physicians. There has been an increase in the use of type specific serums.

Forty-three new typhoid carriers have been added to the register. Twenty-seven of these were discovered through epidemiologic investigation of sporadic cases, 10 by means of release cultures, 3 through attacks of acute cholecystitis, 1 through an attack of acute cystitis, 1 through a costal osteomyelitis with typhoid bacilli present in the discharging pus, and 1 through investigation following the discovery of a positive Widal reaction in a specimen of blood submitted for another purpose. The total number of carriers on the register is now 412.

The number of cases of diphtheria reported in 1938 is the smallest on record. Thirty counties have no cases as compared with 18 such counties in 1937. In the large cities diphtheria is almost under control. Buffalo had 12 cases and Rochester 7, in 1927 there were 737 cases in Buffalo and 505 in Rochester. Of 74,586 individuals reported as having received active immunization, 45,915 were children under 5 years of age. The figures in this paragraph are subject to revision in the final report.

Since the enactment of the Desmond and Twomey bills requiring submission of specimens from applicants for marriage licenses and from pregnant women, the number of serologic examinations made in the laboratory has increased by 63 per cent.

At the end of the year 170 cases of syphilis had been discovered upstate as a result of premarital examinations, and reports on 85 patients were pending. One hundred and twenty-six cases had been found as a result of prenatal examinations, and reports were pending on 23. There were 4,860 new admissions for syphilis to upstate clinics during the year.

The State Institute for the Study of Malignant Disease has provided diagnosis or treatment for 38,628 patients, and has submitted reports on 10,623 specimens of tissue sent to it by physicians throughout the state. They have carried on an ex-

tensive educational campaign having provided lectures on cancer to popular audiences totaling about 25,000 people.

The Narcotics Bureau has also engaged in an educational campaign, using films to demonstrate to audiences of specially interested individuals the characteristics of the hemp weed. Seventy-two thousand, three hundred and twelve pounds of Cannabis have been destroyed, 2,000 pounds of viable seeds have been confiscated, and more than 4,000 marijuana cigarettes have been seized. In the years 1935 to 1938 inclusive, 458 tons of marijuana have been destroyed.

The Public Health Nursing Division reports an increase of only 28 nurses employed by county boards of supervisors. Although this leaves the service disappointingly inadequate, Miss Sheahan believes that there is a better understanding throughout the state of the handicap which all public health work must suffer through this deficiency.

Lead Nipple Shields Prohibited

On January 20 the Public Health Council amended the Sanitary Code by inserting a regulation which prohibits the sale or use of metal or foil breast nipple shields made of or containing lead. The regulation went into effect on February 1.

"Health News" announced that this regulation had been passed "following the death of an infant from lead encephalitis." The authorities at one hospital where lead shields are used have expressed some surprise that so drastic an action should have been taken on the basis of a single case. The case in question was, however, quite definite. It will be published shortly by Dr. Murray H. Bass, whose report will show that lead was found in large amounts in the infant's blood and urine. The death of a child was hardly necessary to prove the existence of a hazard of lead poisoning. The manufacturers claim for the shields that they prevent and cure sore nipples by means of a solution of lactate of lead in which the nipple is immersed. If the mother's nipple is immersed in lactate of lead it is quite evident that her child is in danger of absorbing

lactate of lead with the mother's milk. Colic, even convulsions, in an infant would not readily be attributed to lead poisoning, especially if the attending

physician is unaware that a lead nipple shield is in use. The hazard is certainly present and poisoning may have been more frequent than anyone knows

DOCTORS URGED NOT TO OVERDO SCIENTIFIC TESTS

Dr Walter C. Alvarez of the Mayo Clinic Rochester Minn warned 300 of his colleagues on January 13 that the greatest curse of modern medicine is the desire of many doctors to employ elaborate laboratory tests and x rays to detect ailments when the simple process of talking to patients observing their symptoms and studying their case histories would often accomplish the same or even better results. He spoke before a regular Friday afternoon meeting at the New York Academy of Medicine, 2 East 103rd Street.

Dr Alvarez, who is regarded as one of America's outstanding diagnosticians attacked the belief which he said was current among medical men that all sorts of laboratory tests must be done for every case that comes our way. He urged doctors, instead to use your eyes, ears, fingers and wits and you will often find there is no need to waste time and patients' money in elaborate clinical explorations.

"I spend a great part of my time fighting with young physicians and assistants who have been trained in the best medical schools of the country to keep them from giving patients complete overhauls where they are not necessary. This laboratory examination technique is often valuable, but there are definite common-sense limits to its use. Many diagnosticians who use it extensively would do better to go back to the medicine of their fathers."

Dr Alvarez's subject was Functional Digestive Disturbances, and he outlined the case histories of many of his patients whom laboratory tests showed to be suffering from ulcers, gallstones colitis and similar digestive tract ailments. He recalled dozens of these cases where dangerous and expensive operations to relieve these troubles would not or did not materially help the patients.

"By simple, old-fashioned diagnosis—conversation and probing of family and individual history—I have found many of these people to have nervous breakdowns, neuroses or even marital troubles which led to their suffering. Removing the minor functional ailments shown up by x rays and laboratory tests could do nothing to relieve the fundamental causes of their complaints," he said.

Dr Alvarez recalled a story about the reaction of Dr Oliver Wendell Holmes when he found one of his patients reading a medical book in a Boston library. Dr Holmes, according to Dr Alvarez, tapped the man on the shoulder and remarked "You had better not do that old fellow some day you'll die of a misprint."

Many people are dying today from misprints, in the form of misleading laboratory diagnoses, Dr Alvarez added. Disease and functional troubles which might never cause trouble are brought to light and nervous patients worry themselves to death.

NEW FILM GLORIFIES THE RURAL M D

The country doctor who has won the public's heart in recent "best sellers" is now making his appearance in the flickering films. The courage, unselfishness and public spirit of an unassuming rural physician, and his effect on a little town after twenty years of ministering to it forms the principal theme of a new RKO Radio Picture entitled "A Man To Remember." Edward Ellis, one of the screen's best known character actors has the finest role of his career as the doctor hero of this unusual story based on Katherine Haviland Taylor's "Failure."

The contrast between the doctor's generosity and the penny pinching short sightedness of the town's business leaders coupled with the romance between the doctor's ambitious son and his ward are two phases of the story that help make up its general human appeal. Various incidents of the doctor's career are dramatized in what might be termed "chapters" each suggested by some paper found among his possessions when he dies, and each leading up to the final triumph of his life in the little town that learned to love him.

The Woman's Auxiliary

To the Medical Society of the State of New York

Nassau County

The regular monthly meeting of the Woman's Auxiliary to the Medical Society of the County of Nassau was held in the Auditorium of the Nassau Hospital on January 31, 1939. Mrs. Luther Kice of Garden City presided. Each committee chairman reported on the work her committee was doing. Following the business session, Mr. Dwight Anderson, Director of the Public Relations Bureau of the Medical Society of the State of New York, gave an interesting talk on "What Every Woman Knows."

Mrs. T. Maloney and Mrs. Henry Smith were hostesses at the tea which followed the meeting.

Onondaga County

A meeting of the Woman's Auxiliary to the Medical Society of the County of Onondaga was held on February 7, 1939, in the home of Mrs. H. G. Weiskotten. The guest speaker was Dr. C. Grove Haines of the history department of Syracuse University. His subject was "Italy of Today." An interesting discussion followed.

Queens County

A dessert-bridge was held by the Woman's Auxiliary to the Medical Society of the County of Queens on February 8, 1939. The auxiliary members and their friends enjoyed a very delightful afternoon party arranged by Mrs. Robert Yanover, chairman of entertainment, and her committee. It was gratifying to the president, Mrs. William Lavelle, to see so many present for it was the first social function of the year. Mrs. Lavelle spoke a few words of greeting to the members and guests and hoped that she would welcome them again at other affairs.

Rockland County

A meeting of the Woman's Auxiliary to the Medical Society of the County of

Rockland was held on January 17, 1939, at the home of Mrs. S. W. Toms in Nyack. Mrs. J. C. Dingman presided for the first time. Reports of the year's work were given by the various committee chairmen. Subscriptions to the magazine *Hygeia* had been placed in nine libraries in the county by the Auxiliary. The guest speaker of the afternoon was Dr. Harold Heller, chairman of Economics of the Medical Society of the County of Rockland, who discussed "Socialized Medicine and Its Effect upon Doctors."

The Auxiliary sponsored an essay on "Cancer Control" in the high schools of the County and gave three prizes.

A social hour followed the business meeting and program.

Schenectady County

The Woman's Auxiliary to the Medical Society of the County of Schenectady met at Sunny View on January 24, 1939. Mrs. W. Howard Pillsbury gave a talk on "Current Literature."

On February 6, Mrs. A. H. Congdon was hostess to the Executive Board of the Auxiliary. Programs for the February meeting were discussed.

Letter from Mrs. John J. Buettner, Chairman of Convention

"With spring but a few weeks away, the time has come to remind you of the convention of the Woman's Auxiliary, to be held in the Onondaga Hotel, Syracuse, April 24-26, in conjunction with the 133rd Annual Meeting of the Medical Society of the State of New York.

"The wintry days have found us busy in preparation, and we have planned many attractive and enjoyable events. You will find meetings profitable to attend, and of course you will want to devote some time to the Hobby Show, which each year includes a wide range of interests. Why not send us an exhibit?"

"On the evening of April 24 will be the delegates' dinner, to which we cordially invite all physicians' wives and their friends

"This will be a delightful evening, especially with such an outstanding entertainer as Henry Scott, pianist and humorist. A product of Syracuse University, Mr Scott has met with acclaim in many cities.

"There are several other features about which we will tell you later

"Mrs Daniel J Swan, your state president, will be happy to greet you and all physicians' wives, and you will meet many friends, old and new

"Please come, and do not fail to register with the Woman's Auxiliary of the Medical Society of the State of New York."

"BEST HEALTH RECORD IN HISTORY"

A record low death rate of 10.8 per 1000 population and the highest birth rate in four years gave New York in 1938 what the State Department of Health terms its "best health record in history"

Dr J V De Porte, director of the State Bureau of Vital Statistics, reported a 1938 birth rate of 14 per 1000 population and said births increased 8000 over the previous year while deaths dropped 7000

"The absence of extremes in weather, despite the tropical hurricane of September 21 and the relatively low occurrence of most of the serious communicable diseases" he added were main factors in the uncommonly high level of the physical well-being of the people of the state'

Dr De Porte said infant mortality last year forty-one deaths per 1000 live births was 9 per cent under the 1937 record while maternal mortality thirty-six deaths per 10,000 total births represented a 41 per cent decline over five years

Discussing deaths from causes associated with childbirth Dr De Porte said, it is impossible to ascertain all of the causes of the recent precipitous drop in the New York State rate.'

There is general agreement that newly developed procedures in the treatment of morbid puerperal conditions were responsible for a considerable share of the improvement, he added, and that without doubt better obstetrical practice has also been a factor of decided importance'

He said the heart disease group with a record high mortality rate of 350.4 per 100,000 population was the leading cause of death at all ages' in 1938 with cancer 148.9 also a record mark second in importance.

The death rate from influenza, 3.6 was a record low while pneumonia 61.3 was 27 per cent below the 1937 rate. Other low marks were reported for tuberculosis all forms, 48.2 typhoid and paratyphoid fever 0.4 and homicides, 3.1. Suicides were 16.8 the same mark as in 1937

ANNOUNCEMENT OF VAN METER PRIZE AWARD

The American Association for the Study of Goiter again offers the Van Meter Prize Award of Three Hundred Dollars and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. The award will be made at the annual meeting of the association which will be held in Cincinnati, Ohio on May 22, 23 and 24, 1939 providing essays of sufficient merit are presented in competition.

The competing essays may cover either clinical or research investigations should not exceed three thousand words in length must be presented in English, and a typewritten double

spaced copy sent to the Corresponding Secretary Dr W Blair Mosser 133 Biddle Street, Kane Pennsylvania, not later than April 15, 1939. The Committee which will review the manuscripts is composed of men well qualified to judge the merits of the competing essays

A place will be reserved on the program of the annual meeting for presentation of the Prize Award Essay by the author if it is possible for him to attend. The essay will be published in the annual Proceedings of the Association. This will not prevent its further publication however in any journal selected by the author

Medical News

General

THE radio listeners had an opportunity to hear a fine discussion of the subject "Do We Need a National Health Program?" on February 5. What is known as the "People's Platform," under the leadership of Lyman Bryson, brought together Dr. Clarence G. Bandler, past president of the New York County Medical Society, Dr. Thomas P. Farmer, of Syracuse, chairman of the Public Health Committee of the Medical Society of the State of New York, Dr. Michel M. Davis, chairman of the National Committee on Research and Medical Economics, and Dr. Kingsley Roberts, director of the Bureau of Co-operative Medicine.

Mr. Bryson directed the discussion by saying that "What the public wants to know is whether we are as healthy as we might be. They have a suspicion that the people could be healthier if American resources for health were used better."

Dr. Roberts agreed, and said "Why not try some method for doing it?"

To this Dr. Bandler replied "That, of course, is the great aim of the entire medical profession. We are elaborating plans, we have been elaborating plans." America's unrivaled health record was then cited by Dr. Farmer, who added that "despite what we have accomplished, we should nevertheless try to do more. On the other hand, with this record, we should be very very careful in making any change."

A widespread "dissatisfaction with the financial aspects of medical service" was brought up by Dr. Davis, who had found a feeling that "the present system of paying for medical care doesn't deliver the service, despite the fact that we all know the doctor wants to give it." There is an undeniable "need for expansion of medical care," stated Dr. Roberts.

This was frankly admitted by Dr. Bandler, but he pointed out that "the facilities throughout these United States, in every one of the 48 states and terri-

tories, are there, and doctors can very well distribute those services largely through the medium of their county societies and their state organizations, and I feel that we do not need any further supervision for the purpose of dispensing more service."

"Why is it," asked Dr. Roberts, "that organized medicine, or whatever you want to call it, constantly has fought attempts at new methods to bring medical care to the lower income groups?"

"That is a very unfair statement," exclaimed Dr. Farmer. "I don't think organized medicine has ever fought new methods. It wants the American people to have the best medical care possible. It does not want to give up a method it is using now, which has produced such fine results, for some untried system that worked well in some foreign country different from ours."

"As for a national health program, we have one now," remarked Dr. Farmer a little later. "We do have a national health program. This is an expansion of our present program, and that is something the public really ought to realize, and I am afraid they are forgetting. One of the first duties, I think, in our national health program should be a co-ordination of all present agencies that we have to deal with health and disease, and that should be the first step in any program we have."

"I'm surprised," put in Mr. Bryson, "that the issue of the personal service of the physician to his patient doesn't arise in a conversation of this kind."

"Well, Mr. Bryson," replied Dr. Bandler, "at the present time physicians are contributing in service, summed up in dollars and cents, about a million dollars worth of service, each and every day. They're doing that voluntarily. They're doing that through the medium of existing agencies, and by their own personal effort. If there were a form of compulsory health insurance, or any compulsion, I doubt

very much if that voluntary one million dollars worth of service each day would still be forthcoming. It would have to be paid for by the government."

"That would raise the cost of service

to the people," remarked Dr. Farmer. "Undoubtedly," agreed Dr. Roberts.

The broadcast lasted thirty minutes, and only the high spots of the discussion are given here.

Counties of New York State

Albany County

Dr. Russell L. Cecil, Professor of Clinical Medicine, Cornell University Medical College and Associate Visiting Physician, New York Hospital, spoke on "The Modern Aspects of Pneumonia Therapy," before the Medical Society, County of Albany, on February 15.

Cattaraugus County

The first of a series of lectures and demonstrations on pediatrics and specialized subjects of medicine was held on January 15 in the staff room at St. Francis Hospital, Olean, under the auspices of the Cattaraugus County Medical Society, arranged by its Maternal Welfare Committee.

The County Medical Society has extended an invitation to all members of nearby societies to attend the series, at which the lectures will be given by outstanding authorities of the State Society.

The subject discussed on January 15 dealt with the responsibility of the family physician in preventing behavior problems. Dr. Marvin Israel, Buffalo, was the lecturer.

Dr. Jacob E. K. Morris, of Olean, died at his home there on January 23, at the age of eighty-two. The *Olean Times-Herald* concludes an editorial tribute by saying:

"He was a good citizen—an American gentleman in every sense of the term. Olean will miss him. Another 'beloved physician' has passed on."

He began practice there in 1886.

Chautauque County

"Mental Diseases and Their Management," was discussed by Dr. Earle V. Gray, superintendent of the Gowanda State Homeopathic Hospital, at a dinner

meeting of the Jamestown Medical Society on January 28 at the Hotel Jamestown. Dr. Homer M. Wellman, president, presided. A discussion followed the address.

"Social Medicine," was discussed on February 23 by Dr. Joseph S. Lawrence, state executive officer, New York State Medical Society.

Other meetings of the society are scheduled as follows:

March 30—"Common Abnormalities Seen in Patients before and after Operations," Dr. Frederick A. Collier, professor of surgery, University of Michigan, Ann Arbor.

April 25—"Gynecology," speaker to be announced.

May 25—"Urinary Infections and Their Management," Dr. Oscar J. Oberkircher, Buffalo.

June 29—Spring golf tournament, election of officers, Moon Brook Country Club.

All meetings, with the exception of the last named, are scheduled for the Hotel Jamestown.

Officers of the society are: president, Dr. Homer M. Wellman, vice-president, Dr. Henry G. Morris, secretary-treasurer, Dr. Darwin C. Perkins.

Eric County

The following program for this year was presented by Dr. Carlton E. Wertz, the new president of the Medical Society, County of Erie, in his inaugural address before the society on January 16:

1. To create fellowship and understanding among our members.

2. To create a better feeling with the public.

3. To encourage and co-operate with the Buffalo Department of Health in all

public health matters and preventive medicine

4 To encourage postgraduate instruction

5 To put into operation as soon as possible the nonprofit Medical Indemnity Insurance

6 To continue efforts to obtain compensation for the care of the medically indigent as voted by the society

7 To enlarge the society's office, provide needed new equipment, and full time help in order to provide members with more and better services

8 To establish a lay grievance board to listen to and settle in friendly manner all disputes in regard to bills or other complaints

9 To counteract the unwarranted attacks on the profession, the need for a publicity agent is great to keep the public informed as to the good work being done by organized medicine in education, preventive medicine, higher educational and postgraduate standards, and its willingness to punish its own members if the occasion arises. This is all being done for the welfare of the general public

10 To oppose further progress of the hospitals in the practice of medicine. Hospitals should assist, not compete with private physicians

Some of the groups advocating governmental control of the practice of medicine are sincere, but others are "very definitely crackpots," Dr Arthur W Booth of Elmira told the Erie County Medical Society at a meeting in Buffalo, on January 16, as reported in the *Elmira Star-Gazette*

Dr Booth, a trustee of the American Medical Association and former president of the Medical Society of the State of New York, was the principal speaker at the Buffalo meeting

"The recent proposal of governmental control of the practice of medicine as an efficient means of providing what is lightly called 'adequate medical care for all the people' is the culmination of several years of discussion and agitation by various groups of ambitious welfare workers and

professional social uplifters," declared Dr. Booth

"Some of them are sincere and others very definitely crackpots"

Already beset by controversy which has impeded progress, the Erie county welfare department's elaborate \$245,000 plan to pay Buffalo physicians for treatment of the indigent sick has struck another snag threatening to disrupt the scheme, reports the Buffalo *Courier-Express*

The local relief administration discloses that the state welfare department has served notice it will not reimburse the county for a large portion of the projected expense. Thomas W H Jeacock, county welfare commissioner, revealed that he has been so informed by Harold S Tolley who is local area director for the state agency

At the same time, Mr Jeacock warned that the ultimate result of the state's stand may be scrapping of the whole proposal. He expressed the hope that such an end could be avoided by adoption of a different scheme

From sources close to the Board of Supervisors came strong indications that the board would not approve any setup which carried such a large part of non-reimbursable cost.

Briefly, the plan contemplates the payment of doctors for services given to the city's 85,000 home relief clients at definite rates of \$2 per home call and \$1 per office call. No practitioner would be paid more than a total of \$50 in any one month

Welfare recipients in Buffalo are now treated free by the medical profession, although doctors in the rest of the county have been receiving fees from the welfare administration for some time

Dr Lous Hamman, of Baltimore, addressed the Section of Medicine of the Buffalo Academy of Medicine on February 8 on "Chronic Infections at the Bases of the Lungs," and on February 15 the Section of Obstetrics and Gynecology heard Dr A D Campbell of Montreal, on "The Damaged Birth Canal and Its Repair," and Dr Milton E Kahn, on

"Recently Recognized Special Ovarian Tumors"

Fulton County

Dr Edward K. Cravener, of Schenectady, was guest speaker at a meeting of the Medical Society of Fulton County, held in the Hotel Johnstown, on January 19. He spoke on "Treatment of Fractures of the Forearm."

Dr James A. Shannon, newly elected president, conducted a brief business session and introduced the visiting physician.

Refreshments were served. There were thirty five members in attendance.

Greene County

The proposed public health nurse project for Greene County was endorsed for a trial period of one year at the meeting of the Greene County Medical Society on January 10.

Sponsored by the Greene County Tuberculosis Association, of which Miss Mary A. Deady is now president, the public health nurse program calls for three nurses to be employed by the county, in addition to the two now on duty.

The Medical Society discussed the situation with Dr Ingraham, local representative of the State Department of Health, and decided to recommend to the Board of Supervisors the plan of employing the three public nurses for a trial period of one year, at the end of which time the real value of their services will have been determined.

Kings County

Dr Philip I. Nash, newly installed president of the Kings County Medical Society, condemns the present procedure of naming laymen to lunacy commissions, and urges the society to take the initiative in the drive to have the panel composed only of medically trained men.

Addressing more than 500 doctors in the association's headquarters, 1313 Bedford Ave., on January 17, Dr Nash said that the borough medical group must take the lead in the matter and not wait

for the laity to introduce laws that become strictly medical.

"The system in our courts by which lunacy commissions are appointed," he said—"namely, one psychiatrist, one attorney and one layman—has not only been disapproved by the Brooklyn Bar Association but also by legislators and physicians acquainted with this subject."

"It is my belief that this commission should consist of a panel made up entirely of medically trained men, equally divided between qualified psychiatrists and other medical men who have had experience in the examination of mental cases."

Dr Nash, outlining a comprehensive program for organized medicine in Brooklyn, recommended establishment of a voluntary health indemnity plan which would adequately furnish medical care to borough residents and at the same time protect the interests of the doctor. He also suggested other public health activities, including an increase in the supervision of the milk supply of the underprivileged class.

Reasserting his platform of progressivism which elected him in the first contested election in more than a score of years, Dr Nash criticized the operation of the city's health centers and proposed remuneration and pensions for doctors rendering services in dispensaries and clinics.

Dr Judson P. Pendleton was given a dinner at the Hotel St. George on January 21 on his retirement as visiting pediatricist at the Coney Island Hospital and the Kingston Avenue Hospital after he had reached the age-limit of 65. The staffs of the two hospitals joined with the Coney Island Hospital Alumni Association in the testimonial.

The Doctors' Club of Brooklyn held its annual dinner-dance in the ballroom of The Towers Hotel on January 29.

Installation of the following newly elected officers took place: Dr Edwin A. Griffin, president, Dr Harry Mandelbaum, vice president, Dr Frank Moskowitz, secretary, Dr Siegfried Block, treasurer, Dr Leo Loewe, chairman of

the board of directors and Dr Karl Kaplan, vice-chairman of the board

Members of the Brooklyn Academy of Pediatrics attended a dinner on January 25 in the Hotel Granada. The dinner was followed by a scientific session in the Kings County Medical Society building, 1313 Bedford Ave.

Speakers included Dr Dorothy Andersen of the Babies Hospital, Manhattan, Dr Cornelius P Rhoads of the Rockefeller Institute, Manhattan, Dr Sidney V Haas of Manhattan and Dr Bernard Benjamin of Brooklyn. Dr Miner C Hill, president of the group, presided.

Dr John Bion Bogart, former president of the Brooklyn Surgical Society, and a founder of the American College of Surgeons, died in Middleton, Nova Scotia, Tuesday, January 17. Dr Bogart was seventy-nine.

For twenty-five years Dr Bogart was one of the leading consulting surgeons of Brooklyn, serving in that capacity at the Methodist Episcopal Hospital, where he was directing surgeon, at Kings County Hospital, at Coney Island Hospital, at Jewish Hospital, at the Brooklyn Home for Consumptives, at the Unity Hospital, and at the Wyckoff Heights Hospital, all in Brooklyn. Seven years ago he gave up practice in Brooklyn, returning to his native Nova Scotia.

Among the subjects upon which he published studies were the Aachen treatment of syphilis, empyema of the thorax in children, spinal anesthesia, and mammary tumors with metastases. One of his most notable achievements was the location of the point of entry of the scarlet fever germ in 1918.

Since 1926, when throat trouble made it necessary that his vocal chords be removed in a rare and delicate operation, Dr Bogart had appeared before scientific groups at intervals demonstrating a mechanical reed device for speaking on which he and the Bell Telephone Laboratories of New York collaborated. The device cost \$50,000 and made normal speaking possible.

Nassau County

The Nassau County Medical Society on January 31 heard an address on "Serum Therapy and Chemotherapy in Pneumonia," by Dr Jesse G M Bullowa, physician, Harlem and Willard Parker Hospitals, consulting physician, New York Infirmary for Women and Children, Consultant in Serum Therapy, Long Beach Hospital.

New York County

Dr Leopold Jaches, professor of radiology at Columbia University, who founded and later directed for thirty years the x-ray department at Mount Sinai Hospital, Fifth Avenue and 100th Street, died on January 23 at Mount Sinai Hospital after an illness of four months. He was sixty-six.

The Society of Medical Jurisprudence, on February 13, discussed the question "Should Euthanasia Be Made Lawful?" Speakers were Foster Kennedy, M D, Oscar Riddle, Ph D, and Charles E Nixdorff, Esq.

The Patrolman's Benevolent Association of New York City, Joseph J Burkard, President, has granted to Dr Charles J Dillon, chief surgeon, \$6,000 for the modernization of the x-ray plant at Police Headquarters.

Onondaga County

The feature of the February 7 meeting of the Onondaga County Medical Society was a moving picture entitled "A Trip Around the World," taken by Dr Marshall W Dyer on his recent trip.

A full page article concerning the medical profession will appear in the Centennial Edition of the *Syracuse Journal* in April.

Ontario County

Recommendations that the Ontario County Medical Society support a radio program over a two months' period, presented by the public relations committee, were approved at the first quarterly

meeting of the year, held at the U S Veterans' Hospital on January 10, with Dr Hans Hansen manager, and Dr Parker G Borden, clinical director, as hosts Dr A. W. Armstrong, newly elected president, presided

Short talks by society members, with possible dramatizations, will be included in the 10-minute programs to be presented weekly over Station WMBO, Auburn, in the near future Dr Bryant C Hurlbutt, of Seneca Castle, chairman, Dr Don M. Griswold, district state health officer, and Dr Chauncey W Grove, both of Geneva, are the public relations committee investigating and promoting the project.

The next meeting, April 11, will be in Clifton Springs, and the July meeting in Geneva.

Dr William A. Groat of Syracuse, president of the Medical Society of the State of New York, was the speaker at the meeting of the Geneva Academy of Medicine, at the Geneva Country Club on February 16 Dr Groat's subject was "Home Treatment of Diabetes Using the Newer Types of Insulin"

Dr John H Pratt, of Manchester, was elected president of the Canandaigua Medical Society on January 12 at the annual meeting in the home of the retiring president, Dr Robert M Ross, at Bringham Hall Dr Margaret T Ross remains vice president and Dr James F Maltman succeeds Dr C Harvey Jewett as secretary and treasurer

Following the business meeting and dinner, served to 17 members and one guest, Dr Robert J Stem, assistant physician at the Hall, Dr Ross gave the president's address His topic was "Importance of the Emotions"

Putnam County

Dr Frank Vero, assistant dermatologist, Vanderbilt Clinic, addressed the Putnam County Medical Society at the January meeting upon the subject "Common Skin Diseases in General Practice." The discussion was opened by Dr Camille

Kereszturi and the meeting was held at the offices of Dr Donald W Richie, Croton Falls, N Y

—Reported by John G Jenkin, M.D., Sec

Queens County

The Medical Society of the County of Queens, on January 31, listened to addresses on "Current Economic Trends in Medical Practice" by Dr George D Wolf, author of *The Physician's Business*, and on "Refugees Unlimited" by William Alan Richardson, Esq., Managing Editor of *Medical Economics* Recent Friday afternoon talks February 3—"Adolescent Fractures of the Radius and Ulna and Their Treatment," by Dr Donald Esterbrook McKenna, Orthopedic Surgeon at Brooklyn and M.E., Consultant Orthopedist at Swedish Hospital February 17—"Diagnostic Factors in the Disease of Gallbladder and Bile Ducts," by Dr Charles Gordon Heyd, Surgeon at Postgraduate Hospital

Dr John H Barry, who retired last fall after more than thirty years' service as Queens Sanitary Superintendent of the Department of Health, was the guest of honor, February 2, at the Long Island Medical Society's annual dinner at the Hotel Commodore, Manhattan

The Rockaway Medical Society gave an old fashioned beefsteak dinner on Thursday night, February 2, in the Lawrence Country Club

Dr Carl Boettger, president of the medical board and director of medicine at the Queens General Hospital, and president of the Queens Borough Tuberculosis and Health Association, died on February 1 at his home, 22 DeKoven St., Forest Hills, after a brief illness He was a former president of the Queens County Medical Society and of the Second District branch of the State Medical Society

Rensselaer County

At the January meeting of the Rensselaer County Medical Society Dr Hugh

V Foley, retiring president, delivered his farewell address

A paper on "Common Macrocytic Anemias" was read by Dr Crawford R Green

Schenectady County

The Schenectady County Medical Society has been invited by the directors of Sunnyview Hospital to hold its meetings in the auditorium of the institution. At a recent directors' meeting it was decided to take the action in appreciation of the co-operation of members of the medical society in the work for crippled children at the hospital. Many members of the society are connected with the Sunnyview surgical and medical staffs

Warren County

Members of the Glens Falls Academy of Medicine participated in a program on "Osteogenic Sarcoma," on January 26 in the Crandall Library Auditorium. The meeting was preceded by a dinner at The Queensbury

Dr Herbert A Bartholomew presented two cases of "Osteogenic Sarcoma." One of these cases Dr Bartholomew had followed after the death of Dr Conrad Hoffman, a fellow of the local Academy of Medicine. Dr John H Sheldon also presented a case of the same disease

Continuation of the subject was given by Dr Morris Maslon from the point of view of the pathologist, and by Dr Edgar Birdsall from the point of view of the roentgenologist. Slides and x-ray studies on the screen were shown in connection with these presentations

General discussion on the subject was given by Dr Leroy J Butler, Dr Jesse S Parker, and Dr Irving R Juster. Thirty-five physicians attended, most of them from the Glens Falls vicinity

Westchester County

Dr Samuel A Levine of Boston addressed the Medical Society of the County of Westchester on February 21 on "The Value of Auscultation of the Heart"

Discussion was led by Dr Arthur F Heyl, of New Rochelle

Members of the Westchester County Medical Society, meeting on January 17, were informed of the development of a three-point program for the improvement and extension of medical welfare service to needy and low income groups

The comitia minora announced approval of a plan of medical welfare administration for relief clients to be put into effect in any and every welfare jurisdiction in the county where the local welfare officer and town board subscribes. This program provides for more general participation of physicians in welfare service and supervision of medical service by the County Medical Society, and it establishes a protected freedom of choice of physician for the welfare clients

The executive committee also announced that representatives of the society had presented its proposal for direct medical aid to needy citizens and a plan of voluntary medical expense insurance comparable to the hospital insurance plan at a public hearing of the State Temporary Legislative Commission to formulate a state health program in New York City on December 13, 1938

Dr Ralph T B Todd, of Tarrytown, the society's new president, announced steps to form a citizens' advisory council to confer with representatives of the society. The personnel of the council has not been announced

The White Plains Medical Society held a special meeting at the Gedney Country Club on January 24. Dr Robert C Towse was elected president, succeeding Dr Robert B Hammond. Dr John R Emery was elected vice-president and Dr Harry Klapper was re-elected secretary and treasurer. Doctors Dominic C McElligott and Robert B Hammond were elected to the Board of Governors for two year terms, and Dr Granville F Knight was elected a governor for one year to complete the unexpired term of

Dr Emery The guest speaker of the evening was Mr Clyde Trees, who presented an interesting discussion of the art and science of making medals

At a stated meeting of the Yonkers Academy of Medicine, held at the Amackassm Club, Wednesday evening, January 18, Dr Wilfred D Wingebach, of New York City and Bronxville, discussed the "Care and Treatment of Head Injuries"

In the executive session preceding Dr Wingebach's paper, the Board of Governors announced that a committee of three members of the Academy is to be appointed to confer with the Commissioner of Welfare and to seek a legal opinion from the Corporation Counsel as to the availability of city clinics for people of means, and also to determine what steps may be taken to put an end to what is considered the abuse of public medical

facilities by persons who can afford private medical attention

The Academy contends that free medical services have been made available to persons with both political influence and financial means to the detriment of truly needy persons

Dr William Clarkson Waggoner, fifty-seven, noted eye surgeon and resident of Ossining for the past 11 years, died suddenly at his home, "The Locusts," on Spring Valley Road, from a heart attack, on January 27

Dr George Quincy Johnson, who was medical officer of schools at Ardsley, N Y, died on January 23 at the Dobbs Ferry Hospital, Ardsley, where he had been president of the medical staff He was seventy nine years old

Dr Johnson had practiced medicine since 1882

PREMEDICAL STUDY VIEWED AS WASTE

The lack of stringent educational standards in secondary schools and colleges is tending to produce doctors of "limited quality with the result that the medical profession 'has almost ceased to be a learned profession and has become instead a union of gadgeteers,'" Professor Foster Kennedy of Cornell University Medical School told a gathering of neurologists on February 7 at the New York Academy of Medicine.

Everywhere in the country we are teaching young men and women between the ages of eighteen and twenty two matters which should have been learned between the ages of fourteen and eighteen," Dr Kennedy said. Our colleges, too are not sufficiently high minded in their requirements. The obligatory premedical B.A. has outlived its usefulness, and its ubiquity has led to its degradation.

Dr Kennedy urged the elimination of the present college course for men and women seeking to enter medicine. He said an examination that would eliminate the unfit and that would point to the men and women of high qualifications might serve as a means to choose qualified en-

trants for medical school. By saving the four years now expended in college courses, the medical man when ready to practice medicine, would be able to do so at an earlier age than is now possible and would have a longer time to make use of superior brains" Dr Kennedy declared

He said he was 'distressed' by the advanced age of those now beginning medical careers He characterized as 'imposed infantalism' the present prolonged sojourn in the nurseries of the medical profession. He argued that schools and universities had been sacrificing quality standards to duration and that ritual education is devouring our youth by its great prolongation and intellectual sterilization."

Dr Kennedy concluded that the principal aim of education should be not toward factual stuffing, but toward a higher development of the thinking powers of men and women. For the prospective medical man sound principles cultured on a scientific outlook are far more important than any store of knowledge he held.

Pneumonia Control

AT THE regular monthly meeting of the Nassau County Medical Society, January 31, 1939, Doctor Jesse G M Bullowa read a paper on "Serum Therapy and Chemotherapy in Pneumonia." The discussion of this paper was opened by Dr Alexander D Langmuir, Medical Consultant, Division on Pneumonia Control of the New York State Department of Health. On February 1 Doctor Langmuir held dry clinics, illustrated by motion pictures, before medical groups at the Nassau Hospital in Mineola, and the North Country Community Hospital in Glen Cove. At noon he spoke to the Floral Park Lions Club which had invited other civic organizations of the community. In the evening he addressed the regular monthly meeting of the Nassau County Public Health Nurses Association.

On February 2 Doctor Langmuir conducted dry clinics at the South Nassau Communities Hospital in Rockville Centre, and the Long Beach Hospital, and addressed a meeting of the Hempstead Kiwanis Club.

On February 3 there was held at the Meadowbrook Hospital a pneumonia seminar consisting of ward and laboratory demonstrations covering the field of clinical and laboratory diagnosis, serum therapy and chemotherapy, a discussion of the care of the patient during the

course of the disease and convalescence, as well as the diagnosis and treatment of complications. The seminar was concluded with a luncheon meeting at which Doctor Langmuir made an address. More than fifty doctors registered for this seminar.

In addition to this activity, the new drug sulfapyridine (m-b 693) is being used experimentally under carefully controlled conditions in Meadowbrook, Nassau, and North Country Community Hospitals, and the Pneumonia Committee is engaged in an attempt to work out a co-operative program with the Rockefeller Institute in the matter of virus type pneumonia.

As a preliminary to this program, Doctor Raymond E Lease, of Oyster Bay, addressed the Glen Cove Rotary Club on January 31 on the pneumonia control program, and the front page editorial of the *Nassau Medical News* consisted of an article by Doctor Langmuir with an editorial comment calling attention to the fact that the New York State Pneumonia Control program originated as a project of the State Medical Society. The fact was commented on that this elaborate program is an answer to the propaganda which charges that only through the communization of the profession can the doctors be made to interest themselves in the problem of preventing needless deaths.

MICHIGAN ACTS ON MEDICAL CARE PLANS

The House of Delegates of the Michigan State Medical Society, at a special session in Detroit on January 9, approved the principles of group hospitalization and group medical service and empowered the Society's Council, in co-operation with hospitals and civic groups, to proceed with plans for the formation of nonprofit organizations to provide these two types of service.

The group protection would take the form of insurance with rates and benefits fixed according

to actuarial studies. Rates for the hospitalization plan would probably range, for care in a ward, from sixty cents a month for a single subscriber to \$1.25 for a family. Benefits would include twenty-one days' hospital care for the first year.

For the suggested medical service plan, an employed subscriber would be entitled to a maximum block of units of service, with an alternative plan based on a time consideration.

LORENZ J BROSMAN Esq

Counsel, Medical Society of the State of New York

An Unlicensed Practitioner of Medicine on Trial for Manslaughter

IN A case before the courts of one of the states on the Pacific coast, the question up for consideration was the circumstances under which a person not licensed to practice medicine, but assuming to do so, could be convicted of manslaughter when a patient under his care died.*

The defendant, one K, was charged in two counts, first, with having unlawfully, feloniously, and through gross negligence and ignorance caused the death of one H, and second, with having unlawfully engaged in the practice of medicine in treating the said H without being licensed so to do. The case was tried by the court sitting without a jury, trial by jury having been waived, and K was found guilty of manslaughter, and also of the misdemeanor of practicing medicine without a license. He was sentenced to a penitentiary term for a maximum period of twenty years. The defendant appealed from the convictions.

The evidence as developed upon the trial indicated that the following was the fact situation

The defendant was a so-called drugless healer, who held no state license to practice medicine. He used the title of "doctor" which he derived from schools of drugless healing which he had attended. It was his practice to prescribe various medicines prepared by some company outside the state, which he sold in the original package.

One H, a robust man of thirty-three years, who was engaged in heavy manual labor had been for three years a patient of a Dr A., a regular practitioner, for the care and treatment of the disease of diabetes mellitus from which he suffered. He had been required to follow a strict diet regulating the intake of carbohydrates, and had taken daily injections of

about fifteen units of insulin. He had seen the said physician every two weeks.

H called to see K, the defendant, and became his patient. He was given no physical examination but was questioned, and he told the drugless healer that he desired to discontinue the insulin treatments for his diabetes. He was told that K could cure the disease by his medicine, and that he should discontinue the insulin as his medicine would not mix with insulin. A new diet was prescribed by K, which did not regulate the intake of carbohydrates. K remarked upon the trial that "insulin is not human—it is not fit for any dog."

The same day as that visit, H went to Dr A. and learned that he was at the time sugar free." He promptly discontinued using insulin, and two days later commenced taking K's medicines, in accordance with instructions furnished to him. In five days he was too ill to leave his home, and in another day he was in bed complaining of general numbness. The next morning Dr A. was called in and found him in a serious condition. He was hospitalized, placed in an oxygen tent, given glucose and saline with insulin. Blood sugar tests were taken, which proved to be so high that a reading could not be obtained. The patient died the following evening in spite of the efforts to save him, and his autopsy gave the cause of death as diabetic coma.

Upon the trial five experienced men from the medical profession testified that insulin with restricted intake of carbohydrates is the only known and accepted form of treatment for diabetes mellitus, and that H could not live without such treatment. K's own testimony was the only support given to the method he had pursued.

The Appellate Court in reviewing the

The group protection would take the form of insurance with rates and benefits fixed according

to actuarial studies Rates for the hospitalization plan would probably range, for care in a ward, from sixty cents a month for a single subscriber to \$1 25 for a family Benefits would include twenty-one days' hospital care for the first year

For the suggested medical service plan, an employed subscriber would be entitled to a maximum block of units of service, with an alternative plan based on a time consideration

Treatment of Obesity

A PHYSICIAN whose practice primarily consisted of obstetrics and gynecology was consulted by a woman about forty years of age who complained of gaining weight and being troubled by a tired feeling. An examination showed that the patient weighed 160 pounds which was an excess weight for her height and over a period of three months he prescribed for her condition. The medication, which he advised her to take, included lutein tablets, thyroidarian compound, and alphasitrophenol. With respect to the use of dinitrophenol, the physician gave her careful instructions as to the method of taking the capsules and the number of capsules to be taken. The patient finally came to the doctor and her weight was down to 143 pounds. She told him she was going to Europe and he advised her, at the time, that her weight was down far enough and she should discontinue taking the capsules as soon as she had finished using a prescription for fifty such capsules which he gave to her that day. He never saw the patient thereafter.

About two and one half years later, a malpractice action was instituted against the physician in which the charge was made that the defendant had been negligent in prescribing alphasitrophenol for the plaintiff. She claimed that at the time she left his care, he gave her a prescription for the said drug and that he advised her to have the same filled from time to time, as necessary, and to continue the use of the said drug. She

claimed in her complaint that the use of alphasitrophenol in accordance with the defendant's instructions continued for a period of nine months coming within the two-year period, before the case was commenced. It was further claimed that the drug caused injuries to her eyes requiring operative removal of cataracts.

Application was made to the Court at Special Term on behalf of the defendant to dismiss the complaint on the grounds that the action was barred by the two-year Statute of Limitations applicable to malpractice actions. The plaintiff's attorney contended that, although the defendant had not actually seen the plaintiff within the two year period, the plaintiff had taken the drug pursuant to his prescription well within said period of time and that under such circumstances the action had been commenced timely. The Court at Special Term ruled that, if the defendant in the case should be found guilty of malpractice, such malpractice occurred and was complete when the instructions were given and, therefore, dismissed the complaint.

An appeal was taken on behalf of the plaintiff to the Appellate Division from the said dismissal and said Court affirmed the decision of the lower Court. The plaintiff also applied for permission to carry the matter to the Court of Appeals but said Court declined to consider the matter further, thereby successfully terminating the litigation in favor of the physician.

CORRESPONDENCE

To the Editor of the New York State Journal of Medicine,

I was very much interested in the article Across the Desk by W S W in our last Journal.

I began my practice in 1870 and am familiar with some of the happenings of those days before we became acquainted with the different breeds of Streptococcus, etc.

But W S W in the last part under the heading of Hitch up the Horse and Buggy' made

a very serious mistake when he speaks about boiling up Aunt Tibby's instruments. In fact no instruments were ever so honored as to be boiled. Most of the instruments used in those days were made with hard rubber handles and would have been twisted out of shape if boiled.

I trust that you will pardon me for the above correction, but it seemed necessary in order to uphold the dignity of our Professional Ancestors.

Fort Edward, N Y

Across The Desk

The Dragoons Are Riding

WHEN everything else fails, call out the dragoons. That is what Louis XIV did when any of his subjects did not agree with him. He "dragooned" them into submission, and his forcible persuasions were called the "dragoonades." The dragoons were so named because they carried "dragoons," a kind of carbine "breathing fire," like a dragon.

That was over two hundred years ago, and Louis the Magnificent is dead and gone, but the method still lives. When people disagree "dragoon" them, breathe a little fire on them, "turn on the heat," as we say now.

Few in this part of the country realize that while we are talking about social medicine, an agency of the Washington Administration has already set up such systems in no less than twenty states. While we debate, social medicine is springing into actuality. The dragoons are riding.

Galloping into the Farm States

It is the Farm Security Administration, formerly Rex Tugwell's Resettlement Administration, that is setting up social medicine all through the farming areas. It is financing what amounts to state medicine for more than 100,000 families, as a part of its farm aid. In the Dakotas alone it is giving to about 77,000 clients medical, surgical, dental, and hospital care at \$2 a month a head, which the Farm Administration pays on an insurance plan. About 3,000 country doctors are enlisted and get 51 per cent of the money, hospitals receive 37 per cent, druggists 4, and dentists 8.

All this was told some weeks ago by Samuel Lubell and Walter Everett in an article in the *Saturday Evening Post* (December 17), entitled "Rehearsal for State Medicine." It was confirmed on December 15 when four officials of the Farm Security Administration presented themselves before the Council of the

Minnesota State Medical Association in St. Paul. Says *Minnesota Medicine*, organ of the Association: "These officials confirmed the astonishing extent of various types of medical services for Farm Security clients described in the article—declared that in each case the plan employed had been worked out by the local county or state medical society—asked the Council to work out some similar plan for care of the farm families of Minnesota who are now receiving loans from the Farm Security Administration."

The "Four Horsemen"

Perhaps we may call these four officials the dragoons, or "four horsemen," of social medicine riding into Minnesota. Their spokesman was Dr. H. V. Meriwether, of the U. S. Public Health Service, and he gave figures differing from those in the *Saturday Evening Post*. There are now "thirty-two different plans in operation in thirty-two states," he said—an increase of twelve states since the *Post* article was written. That's speed. The plans vary, he explained, because the medical societies, in each case, dictated them, and he asked the Minnesota State Medical Association to devise a plan for Minnesota.

His reason, as he stated it, was financial. Many farm families in the lower income brackets, he said, lack medical and dental care, and when such families fail to make payments on their loans, "we find medical and dental problems in every case." "Clearly," he declared, "we can not continue our program successfully without provision for medical service for these farmers." Health is wealth, and the farmer who is able to work can pay something on his loans. Otherwise, otherwise.

Who Pays, and How

Thirty-two different plans may seem like confusion, disorder, chaos, but it

seems that they really crystallize into two types—(a) individual arrangements, and (b) "pool," "insurance," or "cash indemnity" plans.

For an individual arrangement, there is Ohio. In that state the list of doctors who wish to participate goes to the farm clients, the client selects his doctor, and he and the doctor get together to find what the client needs. The Farm Administration provides the funds. In Logan County, Ohio, said Dr. Meriwether, all of the money is put in the hands of the Logan County Medical Society, and the Society's custodian of funds pays the doctors' fees on a pre-arranged schedule until the money runs out. "From then on it is between doctor and patient," but "the doctor must continue in attendance, no matter how the funds hold out."

Turning to the "pool" or common fund plan, the farmer pays a definite sum, about \$12 a year in the South, \$20 to \$30 in the Northwest, and he may call anybody in the Medical Society to take care of him. Once a month the doctor submits his normal fee, and if enough money is in hand, he is paid in full, if not, it is prorated. In actuality, about 72 per cent of normal fees have been paid. In several Iowa counties, the doctor submits to the County Society only an account of his services and the County Society sets the amount. Everything, in fact, is arranged by the County Society, "and I personally believe," declared Dr. Meriwether, "that all of these matters should remain in County Medical Society hands." "I like the Iowa plan," he repeated later, "by which the County Medical Society receives the money, prorates it to members, and disciplines its own members."

A separate problem is presented in North and South Dakota, for in those states "the doctors, as well as the patients, needed rehabilitation if the doctors were to remain in practice there." So the doctors suggested a plan, and the plan has been changed three times, and the

money appropriated has been increased three times. Medical bills are being paid on a 66 per cent basis. The doctors themselves believe, we are assured, that "they are going to work out something in Dakota that may ultimately be of benefit to all medical societies." With this preface, the spokesman for the Farm Security Administration asked the Minnesota State Medical Association to work out a plan for the medical care of its Minnesota clients. The Council referred the request for action to the Committee on Low Income and Indigent Problems, and we may hear more about it later.

The Vital Flaw

However, even a layman can see the vital difference between this plausible set-up and the medical insurance plans now being started by the doctors themselves in various states. The California Medical Association is launching one, and a keen editorial writer of the *Los Angeles Times* pierces to the heart of the whole matter in these trenchant words:

"The immediate difference between state medicine as so practiced [by the Farm Administration] and the medical insurance plan which is being pioneered by the doctors and hospitals in California is that in the former the cost is defrayed in whole or large part by the government, and in the latter by the individual beneficiaries themselves.

Actually, the difference is that between political paternalism on the one hand, and independent self help on the other. The one is open to all the political abuses and chiseling which have made government relief a national scandal, the other, while yet to be tried on a large scale, is at least an intelligent effort to help the poor to help themselves.

The first would turn the Hippocratic profession into another tax financed government bureau, the second would extend its benefits to everyone without the taint of politics or charity."

REVIEWED

Papers on Psycho-Analysis. By Ernest Jones, M.D. Fourth edition. Octavo of 643 pages. Baltimore William Wood and Company 1938. Cloth, \$8.00

The last edition of this well known work came out 15 years ago. Since that time changes and revisions in psychoanalytic concepts have been made, but none as to the fundamentals. All of Dr Jones' papers have appeared in medical and other scientific journals. It would be impossible to single out any one particular article as especially praiseworthy. Jones is in the forefront of the psychoanalytic movement, and he has enriched the psychoanalytic literature by many

original contributions. His learning is prodigious, and there is scarcely a domain in psychology, anthropology, and sexology which did not benefit by his writings.

However, there are many mooted questions in psychoanalysis and many a theory which rests on debatable ground. It is here where one may disagree with Jones. As an illustration one may refer to the chapter entitled "The Theory of Symbolism." Jones adheres to the view that the origin of symbolism goes far back into antiquity, in primeval times. Those savages possessed the faculty of discrimination,

recognized similarities in things first because similarities are easier to grasp and cognize. Similarities are withal more interesting and being interesting, follow the pleasure-pain principle.

Now, all this is highly speculative. We can picture to ourselves the first reaction of the primitive man to a new experience. If not fear-inspiring, it will arouse curiosity. If a similar experience occurs later, a warm feeling of intimacy and understanding results. Interest can attach itself only to experiences which are pleasure producing. Interest is likely to shift from similar objects or qualities to dissimilar things. Dissimilarities are often more striking than similarities and curiosity is more likely to be aroused in strange than in familiar things. All this is interesting reading even if not always convincing.

JOSEPH SMITH

Claude Bernard Physiologist. By J M D Olmsted. Octavo of 272 pages, illustrated. New York, Harper & Brothers, 1938. Cloth, \$4 00.

There has long been a real need for a booklength biography of Claude Bernard in English. The only other English account of Bernard's life was written by Sir Michael Foster toward the end of the last century, and was rather sketchy. Dr Olmsted's book fills this need completely. It is divided into three parts, the first dealing with Bernard's life and his personal affairs. In the second his contributions to physiology are discussed, and the third section sums up his more general speculative and theoretic generalizations.

Dr Olmsted's work is the result of a great deal of meticulous research. Not only did he study Bernard's scientific writings thoroughly and critically, but he also examined sources which had never been utilized, in particular the Rafalovich correspondence. In addition, Dr Olmsted also visited the birthplace of Claude Bernard, and examined the relics of the great physiologist still to be found there. The author succeeds in evoking a clear and human picture of Bernard as a

man and a scientist. The clarity with which he presents the scientific accomplishments of the French physiologist and the critical acumen with which he evaluates these discoveries combine to give an admirable account of Bernard's work.

Dr Olmsted has definitely written a first-rate biography, which can be highly recommended to every physician.

GEORGE ROSEN

The New International Clinics Original Contributions, Clinics, and Evaluated Reviews of Current Advances in the Medical Arts. Edited by George M Piersol, M D. Volume II, New Series One, 1938. Octavo of 315 pages, illustrated. Philadelphia, J B Lippincott Company, 1938. Cloth, \$3 00.

This volume of *The New International Clinics* contains many well written articles on various subjects. Each article is of value, and the titles include a large field: heart surgery, hypertension, encephalitis, insulin treatment in dementia praecox, the foot in general practice, and other subjects. The section devoted to clinics gives valuable presentations on such subjects as the anemias, cortical adrenal tumors, some cases of Bright's disease, renal carbuncles, spontaneous hypoglycemia, and presents a surgical clinic on retroperitoneal tumors, sarcoma of the chest wall, and mixed tumors of the parotid. This volume is another valuable addition to the series.

HENRY M MOSES

Sulfanilamide Therapy of Bacterial Infections. With Special Reference to Diseases Caused by Hemolytic Streptococci, Pneumococci, Meningococci, and Gonococci. By Ralph R Mellon, M D, Paul Gross, M D, and Frank B Cooper, M S. Octavo of 398 pages. Springfield, Charles C Thomas, 1938. Cloth, \$4 00.

Within the past few years a multitude of clinical and laboratory reports have disseminated widespread cognizance of the value of sulfanilamide in the management of infections. This volume unifies such knowledge as completely as the relatively early history of the drug permits. The authors are of the pioneer American

investigators, one of them probably the first treated in this country. Their own experimental accomplishments furnish much material, but the entire field of the sulfanilamide compounds is exceptionally surveyed. Even the very recent developments are included by adding a late section. A useful reference and stimulus for chemotherapeutic research has been furnished, but its greater appeal may be as an authoritative review and summary to the practitioner using this form of chemotherapy.

IRVING M. DERNY

A Textbook of Physiology By William D. Zoethout, Ph.D. Sixth edition. Octavo of 714 pages illustrated. St. Louis The C. V. Mosby Company 1938. Cloth, \$4.00.

This book represents scarcely any change from the preceding, that is the fifth, edition. In general, it is not a textbook of physiology to interest the practitioner of medicine.

G. B. RAY

Nervous and Mental Diseases for Nurses By Irving J. Sands, M.D. Third edition, 12 mo of 321 pages illustrated. Philadelphia, W. B. Saunders Co. 1937. Cloth \$2.00.

In the third edition of this text, the author has rewritten many of the chapters and has included new methods and improvements in the care of mental and nervous diseases. Such revisions and additions have not increased the size of the book. Each disease or disorder is clearly discussed, and sufficient material is included to provide the nurse with what she should know about mental and nervous diseases and their nursing care. This is an excellent textbook, fulfilling the purpose for which it was written and we do not hesitate to recommend it.

O. C. PERKINS

Aids to Physiology By Henry Dryerre, Ph.D. Second edition. 16 mo of 295 pages illustrated. Baltimore, William Wood & Company 1937. Cloth \$1.25.

This little volume is a compendium containing the essential facts found in larger works. It can be recommended,

especially to students and practitioners who wish to review briefly the subject of physiology without consuming considerable time.

MORRIS ANT

Surface and Radiological Anatomy For Students and General Practitioners. By Arthur B. Appleton, M.D., William J. Hamilton, M.D., and Ivan C. C. Tchaperoff, M.D. Quarto of 311 pages illustrated. Baltimore, William Wood & Company 1938. Cloth, \$5.50.

This book is most timely, arriving as it does, at a time when many medical colleges have supplemented their courses in anatomy with roentgenologic instruction. Heretofore, the student in anatomy dealt mainly with the cadaver. With the addition of roentgenologic anatomy, he has the opportunity of correlating his knowledge acquired from dissection with the wealth of undistorted information gathered from the examination of the living subject. Therefore, such study gives not only a clearer concept of anatomy and physiology, but also lays a solid foundation for an understanding and interpretation of roentgenology in health and disease. By the same token, the general practitioner who seeks a basic knowledge of the subject, as well as the embryo roentgenologist, will profit by the study of this short, compact volume.

Although the parts devoted to surface anatomy are in the main adequate for the scope of the book, much important material has been omitted in the sections on roentgenologic anatomy. This is probably due to the authors' desire to limit the size of the volume. Unfortunately, in a few places the old and new nomenclatures are confused and used interchangeably.

On the whole, this book represents a concise, although elementary, presentation of the subject matter which is well printed and orderly arranged, and admirably serves the purpose of a textbook. Liberally illustrated with colored plates for the anatomic drawings and with representative roentgenograms which are clearly labeled, the volume promises to fulfil a distinct need. It is probably a

forerunner of larger and more advanced works on roentgen anatomy and physiology

SAMUEL GEORGE SCHENCK

Chronic Intestinal Toxemia and Its Treatment with Special Reference to Colonic Therapy By James W. Wiltsie, M. D. Duodecimo of 268 pages. Baltimore, William Wood & Company, 1938. Cloth, \$3.00.

It is, perhaps, a good thing that the subjects of "alimentary toxemia" and "colonic stasis" are reviewed from time to time. Often we are inclined to doubt their existence, particularly in view of the work of Hurst and Alvarez which appeared to show that mere insertion of a ball of cotton into the rectum reproduced most of the symptoms of "toxemia." Dr. Wiltsie, in his small book on the manifold functions and certain disorders of the colon, proves himself a firm believer in the theories of chronic intestinal toxemia for which he advocates, among other procedures, a course of colonic irrigations properly done with competent guidance. Case reports are cited to prove the value of his procedure.

Whether the beneficial results be attributed to psychic cleansing or alterative effects, there is no doubt that such irrigations often are helpful. To those interested in knowing more about suitable equipment and the best technic, this book can certainly be recommended.

ANDREW M. BABEY

The Culture of Organs By Alexis Carrel, and Charles A. Lindbergh. Octavo of 221 pages, illustrated. New York, Paul B. Hoeber, Inc., 1938. Cloth, \$4.50.

The problem of maintaining the viability of organs *in vitro*, has concerned investigators for many years. The first report on this subject was made by Le Gallois in 1812. The final success *in vitro* culture of whole organs was made possible with the invention by Charles A. Lindbergh of a coil apparatus in which was incorporated a pulsating mechanism. This apparatus is a device for furnishing an organ with a pulsating perfusion of nutrient material under sterile conditions.

In the first experiment the authors succeeded in keeping a thyroid gland of a cat alive for eighteen days. Subsequent investigations had resulted in maintaining the viability of whole organs for as long as forty days. One of the most remarkable observations that the authors have made consisted of alterations in the structural pattern of organs as influenced by varying the constituents of the perfusion media. They were able to demonstrate hyperplasia of cells and growth of organs *in vitro*.

Lindbergh's experience and mechanical ingenuity are seen in the construction of the apparatus. It consists of two parts: a perfusion apparatus and a mechanism for driving the perfusion fluid by means of pulsating gas pressure.

The chapters concerned with the biology and physiology of organs are contributed by Alexis Carrel. In them one finds a fascinating concept of anatomic structures in their relationship to physiologic time. Carrel considers the functions of organs as the fourth dimension in viewing the anatomic structure of an organ. The chapters concerned with the mechanical development and construction of the pulsating perfusion device are contributed by Lindbergh.

WILLIAM S. COLLENS

A Text-book of Pharmaceutics. By Arthur O. Bentley. Fourth edition. Octavo of 1,001 pages, illustrated. Baltimore, William Wood and Company, 1937. Cloth, \$5.00.

This book, as its name implies, is devoted exclusively to pharmacy and pharmaceutical processes. Unfortunately, it is based on the British Pharmacopoeia. The names of preparations and their standardization are different from those used by American pharmacists and physicians who adhere to the United States Pharmacopoeia. One can recommend, however, the section on biologic assay, which is a clear and comprehensive description of the physiologic standardization of hormones, vitamins, digitalis, and arsphenamine compounds.

CHARLES SOLOMON

NEW YORK STATE JOURNAL *of* MEDICINE

VOLUME 39

MARCH 15 1939

NUMBER 6

Editorial

The Better Way

Nonprofit voluntary cash indemnity insurance combines the best features of private practice and state health insurance. It preserves free choice of physicians and leaves the important intangible elements in healing intact. It protects small wage earners against the financial consequences of prolonged or serious illness. It leaves the responsibility for the standards of medical practice with the profession, where it belongs, and retains the incentives for continuous self-improvement by physicians. By making it easier for the low income class to go to the doctor, it promises to better the public health.

What it does *not* do, is equally important. It does *not* set up two kinds of medical practice, a superior grade for the well-to-do and an inferior one for the small wage-earner. It does *not* reduce the sick worker to the status of a case number, neither does it deprive him of the right to select his own physician or to enjoy the privileges of professional confidentiality. It does *not* set up a political bureaucracy in control of medical care and subject the practitioner to lay supervision and restraints. It does *not* burden the taxpayer with levies for medical care, of which administrative expenses consume a considerable portion.

The Piper bill (Assembly Introductory No. 500) permits the establishment of nonprofit medical cash indemnity insurance in this state. While the State Insurance Law would regulate financial details, medical principles would dictate the medical rules. Unethical solicitation of patients would be forbidden. Medical service associations would be kept separate and distinct from hospital service groups.

The last provision is extremely important. A bill sponsored by Assemblyman Downing would permit hospital service organizations to provide medical care. This is in clear violation of the condition on which the profession supported group hospitalization.

Hospital service associations are firmly established in this state, thanks in large part to the support of organized medicine. To permit them to include physicians' services in their contracts would give them a virtual monopoly of medical care. This they are in no way qualified to exercise—even if the principle of such a monopoly were sound, which it is not.

The management of group hospitalization is in predominantly lay hands. Lay executives, no matter how experienced in social service and hospital administration, are not equipped for the direction of a vast medical service plan.

The Piper bill is superior to the Downing bill by virtue of its detailed grasp of the problem of medical care and its separation of medical and hospital service. It has all the good points of the Downing bill and none of its faults. Enactment of Assembly Introductory No. 500 would set New York State on the way to providing its working population with a sound, simple means of budgeting for health.

A Notable Program

The scientific program of the State Society this year emphasizes early recognition of disease to prevent complications and chronicity and save life. There are two chief factors in failure to secure early treatment. Often the sick postpone going to a doctor until they have tried out various widely advertised proprietary remedies. Sometimes the fault lies with the physician, who does not recognize early symptoms.

Education of the public to seek medical care promptly is an essential element in preventive medicine. Toward the same end, the profession is constantly seeking more accurate diagnostic procedures and a higher development of the clinical diagnostic faculties. The Scientific Program of the State Society responds to this need.

On April 25 the general scientific session will be given over to the early recognition and treatment of emergencies. A series of thirty-minute talks, practical in nature, will clarify fine diagnostic points and clear up any commonly held misconceptions. Dr. Thew Wright, Professor of Surgery at the University of Buffalo, will take up "The Acute Abdomen." "Obstetrical Emergencies" will be covered by Dr. Edward A. Schumann, Professor at the University of Pennsylvania. Dr. Orman C. Perkins, Professor of Clinical

Neurology at the Long Island College of Medicine, will present the subject of 'Acute Cerebral Emergencies', and Dr Edward C Reifstein, Professor of Medicine at Syracuse, "Cardiac Emergencies"

The recognition of chronic disease in its first stages will be covered in similar fashion on the 27th of April Dr Samuel A Levine, Assistant Professor of Medicine at Harvard, will describe 'The Early Evidence of Cardiovascular Disease Early Diagnosis and Treatment of Pulmonary Tuberculosis' will be discussed by Dr James Alexander Miller, Professor of Clinical Medicine at Columbia Dr Clarence O Cheney, Professor of Clinical Psychiatry at Cornell, will take up the "Early Recognition of Mental Diseases and Their Treatment" The A Walter Suter Lecture this year will be devoted to "The Early Diagnosis of Cancer" Dr Francis Carter Wood, Professor of Cancer Research at Columbia, will deliver it

In these eight half-hour lectures, registrants will get a comprehensive, practical review of diagnostic and therapeutic procedure from the point of view of early detection and timely attack The Annual Meeting of the State Society is little more than a month off now Members should start planning their calendars so they will be free to attend

Prevention of Deafness

The problem of deafness still awaits solution However, the outlook now appears considerably more favorable than it did even as recently as ten years ago The amelioration of hearing loss naturally interests both the afflicted and the physician, but a far greater need is the early recognition of the causes of deafness and their removal so that a subsequent diminution in hearing may be forestalled The increase in the number of deafened individuals so concerned our legislature that the examination of the hearing of children in our schools has been made a compulsory measure

It has long been known that a continued obstruction of the eustachian tubes results in a permanent impairment of hearing In children, this is most frequently due to abnormal amounts of lymphoid tissue in the nasopharynx Otolaryngologists have always recommended the removal of adenoids as a prevention against otitic suppuration and deafness, and unquestionably this procedure has had its successes But, according to Crowe and Baylor¹ this does not always relieve the tubal obstruction, since nodules of hyperplastic lymphoid tissue may remain or develop after a cold and

¹ Crowe S J and Baylor J W J A M A 112: 665 (Feb 18) 1939

cause partial obstruction of the eustachian tube Over a period of ten years, these observers have carefully studied sixty children up to fifteen years of age and conclude that the "most common type of middle ear deafness in adults begins between the ages of five and ten years," and is the result of hyperplastic lymphoid tissue around the pharyngeal orifice of the tube Its early manifestation is retraction of the drum, impairment of hearing for the high tones, and good hearing for the low tones

When the condition is recognized, this lymphoid tissue should be kept in abeyance during the period of most active growth The use of small doses of radium, as described by Crowe and Baylor, before permanent middle ear changes have taken place, will not only prevent future development but will restore to normal the hearing loss already present in children below the age of fifteen "We feel that if school children in the primary grades were examined with a nasopharyngoscope at least once a year, and those with hyperplastic lymphoid tissue in and around the orifice of the eustachian tubes were treated with radiation as often as necessary to insure normal functioning of the tubes, the number of deaf adults in the next generation could be reduced by 50 per cent "

Stammering and Allergy

It seems a far cry between stammering and allergic diathesis Commonly it is assumed that this type of speech impediment has a psychologic background—a sense of guilt, inferiority, fear—or it is the result of imitation Kennedy and Williams,¹ however, in a study of 100 consecutive cases of stammering children, found that 52 had a personal history of allergic manifestations Of the remaining 38, there was a family history of allergy in all but one

It is also significant that a family history of stammering was obtained in 65 of the cases observed by Kennedy and Williams This almost constant association of allergic manifestations and stammering as reported in their presentation warrants further investigation by allergists, psychologists, and those who treat speech defects Many conditions hitherto unexplainable have been found to be the result of allergic disorder Such conditions, when present, require individual types of treatment for their alleviation Perhaps this is the reason why no universal form of therapy is applicable to all cases of stammering Latif,² in this connection, considers no treatment of stammering effective unless both primary and secondary factors are taken into account This large series of cases suggests

¹ Kennedy, A. M. and Williams D. A. *Brit Med J* 2 1306 (1938)

² Latif I. *Brit M Med Psychol* 17 307 (1938)

that there may be more than a casual relationship between allergy and this variety of speech defect

Current Comment

"Medicine is a living, vital science, constantly moving to attack new problems that arise. It has given vastly of itself to mankind in the past, and it stands ready to give more, if it can, in the future. It makes to mankind no promise of immortality or even of eternal youth, but it does offer to those who are ready to receive its gifts, increasing years of usefulness." From an article in the *St. Louis County Medical Society Bulletin* of February 17, 1939

"The American people for two or three federal elections past have had the question, 'Do you want socialism?' put to them in the form of a socialist candidate for president. The answer by and large has been most emphatically, No! and yet it would appear that the very thing which the American people in mass turn down, they are willing to swallow if given to them piecemeal.

"There is an old Latin saying, 'divide and conquer, which carried with it a moral. Any task which appears to be huge in its totality may be accomplished by dividing and attempting a little at a time. Compulsory health insurance represents one of these divisions" *Exchange*

And in spite of all this we think that we, as a nation, are smart. Tell the underprivileged of this nation that the government is going to give them \$50,000,000 for medical care for the coming year and the giver gets the votes. On the other hand, tell each one of these 40,000,000 persons individually that the government is going to give him \$1.25

for sickness during the next year and the giver is a louse!

"Yes sir! Fifty million dollars, if all spent for medical care, will give each of the forty millions now receiving inadequate care exactly \$1.25 a year additional care—the price of one single haircut and shampoo." Sedgwick Co (Kan) *Medical Bulletin*

"It has been definitely determined by certain of the governmental agencies that the reason some of our people are poor is because they have no money. Having no money, it follows they have poor housing, insufficient food, lack of proper clothing, and inadequate medical attention. The whole thing is now clear. It has not been emphasized, however, that the proportion of medical care they do have is higher than the proportion of these other necessities due to the philanthropic character of the physicians. If the purveyors of the other commodities were as generous, the entire problem would be ameliorated and there would then be less demand for more medical service.

The time is not yet ripe to release over a broad area a type of medical practice which has been shown to be definitely inadequate. Also until all human beings are cast in the same mold, like peas, it is questionable whether that time will ever arrive.

"The sociologists after all merely aim for a more adequate distribution of inadequate medical service to those in the lower financial brackets. This will keep them sick and keep them poor, but it will make a lot of new jobs, and that's something!" *The Weekly Roster and Medical Digest of Philadelphia* presents "Some of the Other Sides"

"The future is unpredictable, but come what may, the treasured invisible emblem which physicians' shingles have borne through the years must be guarded carefully against any blighting effect of the hysterical paternalism which is sweeping the world. It must never be besmirched or obliterated by the long, crooked, slimy fingers of politics." Elmer H Bobst, in *Rochester Review*, recently

. . .

"'Free Medicine for All'—such is the caption of an article in one of the popular magazines. On seeing this we were reminded of the man who went into a tavern optimistically and left it misty optically. The writer in his enthusiasm for his subject forgot that medical care under any system must be paid for. This mistiness, we have noticed, is quite characteristic of many social reformers." A "Timely Brevity" in the *Milwaukee Medical Times* for February

. . .

"An intensified public relations campaign explaining medicine and its works to the laity is needed now. It would be an eleventh hour remedy but it's worth the trying before the great and gullible American public is sold completely and irretrievably down the river of socialized medicine." The *Illinois Medical Journal* desires that we "Educate the Laity as to the Evil of Tax Supported Medical Practice," and discusses this question in its February issue.

. . .

"Doctors Aren't Villains," states an editorial in *The Katonah Record*, from which we quote in part "Indictment of these doctors seems like a very drastic and 'cocusy' performance as a prelude to a new national health movement. It naturally clouds the movement. The nation's doctors are intimately connected with the home life of the American people. Notwithstanding this fact they are indicted like deep-dyed villains. As a matter of fact there is no profession that

stands higher in the estimation of the American public than our doctors" (Italics ours)

. . .

"I, for one, would like to have the American people know that I personally, as a physician, feel that I have been indicted by the United States government, that the impugned reflection on the integrity of the American Medical Association is considered by me as a reflection upon myself. I should like to have every citizen of the United States know that his family physician has been indicted. Under our American system the medical profession has never defaulted an obligation nor proved unfaithful to a trust." How Dr Henry A Luce, President of the Michigan State Medical Society, feels about the matter.

. . .

"The fight against mental disease is a totalitarian war in which all elements in the population must take their part. Propaganda must be employed, but what we want to propagate is the truth. It is the special role of those who are most closely associated with this special field of medicine to increase our body of knowledge as rapidly as possible, to give additional precision to the general principles which are gradually being outlined to bring the facts within this field of medicine into their natural relationship with other branches of science." C Macfie Campbell, quoted in "The Gist of It," a reprint of the results of the symposium on mental health held recently by the American Association for the Advancement of Science.

. . .

"The standard of knowledge of the general practitioner of today often surpasses the peak of certain specialists twenty or twenty-five years ago." Comment in the *Edinburgh Medical Journal*

MULTIPLE AREAS OF INTRACEREBRAL CALCIFICATION

CHARLES A. MCKENDREE, M D , S BERNARD WORTIS, M D , S E SOLTZ
M D , New York City

(From the New York Neurological Institute and the Department of Neurology Bellevue Hospital)

THE finding of calcification within the cerebral hemispheres is of great importance from the diagnostic, etiologic, and therapeutic points of view. Normally, in adults, calcium deposition often occurs in the pineal body, the choroid plexus, the falx cerebri, and occasionally in the meninges. Aside from these usual sites, any roentgenographic evidence of calcium deposits within the cranium should lead one to suspect either degenerative or neoplastic disease.

As is well known, calcification may occur in mongolism and cretinism,¹ old standing chorea, tuberose sclerosis,² cranial pharyngiomas, various forms of gliomata, angiomas,³ tubercles, meningiomata, subdural hematomata,⁴ intracerebral hemorrhage, aneurysms,⁵ cysts, old abscesses, arterio-sclerotic changes in vessels, old meningeal disease,⁶ cholesteatomata, chronic encephalitis,⁷ etc. In most of these conditions it is unusual to find more than one focal area of calcification, and the x-ray characteristics are quite distinctive from the lesions discussed in this paper.

Multiple areas of calcification within the brain are not found frequently. When present, they have not been associated with similar deposits elsewhere in the body. Weimann,⁸ in 1921, described an extremely interesting case of calcification of cerebral vessels. In his case there were extensive and multiple lesions of the vessels and corresponding brain tissue. In 1929 Parkes Weber⁹ described multiple calcium lesions within the brain associated with cutaneous manifestations such as nevi. These brain lesions were easily demonstrated by roentgenograms as rather shadowy images within the cerebral hemisphere which seemed to follow the course of the af-

ected gyri. The calculi were of considerable diameter, and were patterned in the form of layers corresponding to the surface of the brain. The histologic study of such cases by Krabbe¹⁰ demonstrated the deposits of calcium to be within the second and third layers of the cerebral cortex together with atrophic and sclerotic changes within the gray matter of the area involved. In addition, Krabbe found associated slight angiomatous modifications of the pia mater, and angiomata of the face in the cases he described.

Dimitri¹⁰ and others have reported somewhat similar clinical cases.

In the disorder known as Krabbe's disease, and sometimes as Parkes Weber's disease, one finds mental disturbances, convulsive disorders, vascular alterations in various parts of the cerebrospinal axis, and cutaneous manifestations, together with definite x-ray evidence of calcification within the brain. The vascular disturbances were very slight in the brains of these cases studied histologically, and furthermore the changes within the brain could not be attributed to vascular origin.

An entity described by Geyelin and Penfield¹¹ is closely related to Krabbe's disease, and it is probably difficult to distinguish between them by x-ray evidence alone. In the condition described by Geyelin and Penfield as "endarteritis cerebri calcificans," changes were believed to be present in the terminal blood vessels of the cerebral hemispheres, and to have produced calcium deposits in the cortical substance. Geyelin and Penfield felt that the histologic appearance of the brain was the result of alterations of the blood vessels, and possibly due to an altered metabolism of calcium. Their cases, familial in type,

showed multiple calcium deposits in various regions of the brain, especially the occipital lobe. X-ray photographs showed the concretions to be egg-shaped, somewhat umbilicated in appearance, and following or symmetrical to the marginal gyrations. Their group of cases is related to Krabbe's disease, the distinguishing features of "endarteritis cerebri calcificans" being the absence of cutaneous lesions and angiomatic malformations of the cerebral blood vessels. Furthermore, their histopathologic report lends great weight to the thesis that the primary cause is a vascular disturbance.

Bassoe and Hassin¹² reported a case of pseudo-tumor, in which multiple areas of calcification were noted by x-ray. Pathologic studies revealed the sites of the calcium deposits to be in the tissue spaces of the cerebral cortex, and also in the smaller and larger blood vessels.

In their case the usual changes were primarily within the cerebral vessels, with secondary changes in the cortical substance. The degree of calcium infiltration of the cortex was minimal compared with that of the blood vessels.

The clinical features of Bassoe's case simulated brain tumor, and did not in any way resemble the symptomatology of the cases reported by Krabbe, and Geyelin and Penfield. Operative procedures on two occasions on the left hemisphere of Bassoe's patient gave evidence of a deeply situated hard mass. Histologic study proved a peculiar type of encephalitis, a localized indurated calcified area, and a certain amount of generalized encephalitis in distant parts as well. The capillaries and smaller vessels were infiltrated with a colloid substance found as droplets on the walls, or totally enveloping them.

Careful x-ray studies of intracranial calcifications have been made by Camp,¹³ of the Mayo Clinic.

There have been various suggestions offered to explain the etiology of calcium deposits within the brain. Rukstnat¹⁴ and others believe they are due to birth injury and internal hydrocephalus. Buckley¹⁵ concludes that intracerebral calculi

may be associated with a previous intracranial injury or with an existing vascular hypertension, and feels that they most probably represent the end result of cerebral hemorrhage or degeneration. Bassoe and Hassin believe that calcification of the cerebral vessels themselves are responsible for the changes within the hemispheres. Wells¹⁶ is of the opinion that metastatic calcification is probably the cause of the formation of calculi in the brain.

Whatever the etiology may be in the groups of cases mentioned above, the disturbance is either in the cortical substance itself, with secondary or minimal pathologic changes of the vascular system, or the pathologic focus lies within the vessels of the brain with secondary alterations in the cortical substance.

The absence of altered calcium metabolism elsewhere in the body, and the normal content of calcium in the blood and spinal fluid point to a localized alteration in the brain.

Our case reports may further complicate the clinical interpretation of multiple calcifications within the brain substance, but there are certain points of interest in these 3 cases that are stimulating, not only from the diagnostic point of view, but also from the therapeutic angle.

Case Reports

Case 1—A white female, aged 12, came for office consultation on February 17, 1937. The patient's mother described the following complaints: the child had spells of unconsciousness, and nocturnal attacks of bizarre behavior, lasting a few minutes. She would often sing meaningless words and apparently absurd phrases, or would arise from bed in a daze and walk about, occasionally sinking to the floor rather helplessly. Often she would crawl without apparent cause on her hands and knees. She had injured her hand in some of these performances. Immediately following such episodes, the patient would open her eyes, look at her mother, and become fully conscious, but with no memory of her immediately preceding bizarre behavior. In one attack, she put her head on her mother's shoulder, and her head seemed to shake, and "she felt so cold along her spine," and then suddenly went to sleep.

On November 20 1936 the child seemed in disposed and stayed in bed. The next morning she felt well and went to school. During that afternoon she was seen by one of us (McK.) because she had been hit during play by a light dodge-ball, and her head had struck an adjacent wall. The patient rubbed her head and continued playing ball for five or ten minutes although she appeared markedly pale to one of her schoolmates. Suddenly she went over to a ledge and sat down, and did not offer to join the new game that was starting. When invited, she said that she felt tired. She sat still for about five minutes, and when the game was over she was observed sitting with her head between her hand. A teacher observed that one of her hands was shaking somewhat. She was carried to a couch her talk in reply to questions was unintelligible and she became unconscious and remained so for several minutes. There was no incontinence of the sphincters and no biting of the tongue. The pupils were widely dilated but reacted to light. One hour later the patient was able to return to her home in a cab. She appeared normal in every way but rested at home for a few days.

Six weeks later in the classroom the patient felt queer, and said to a girl sitting next to her 'I can't see. Tell the teacher I want to go to the hospital room.' Almost immediately thereafter she fell to the floor unconscious, had no motor convulsive movements and remained unconscious for five or six minutes. On first recovering consciousness, she did not recognize the nurse, but soon became mentally clear and complained only of fatigue.

On two occasions, the mother heard the patient cry out in her restless sleep sit up in bed and move her lower extremities. When aroused, she expressed fears that her mother was dead, and other definite anxieties.

Past History The patient was a normal birth. She had always been nervous as evidenced by picking or biting her nails. The child began to walk at sixteen months and spoke at two and one-half years. Her general health had been excellent.

The menstrual periods began at eleven or curving at intervals of 21 to 31 days lasting five days rather profuse in amount, without special discomfort.

She had chicken pox measles mumps pertussis, and mild influenza in childhood with no neurologic complications.

There were no hay fever or asthma allergic manifestations but the child had idiosyncrasies to carrots, orange juice, and egg yolk.

Both tonsils and adenoids were removed at the age of three.

Family History The family history was negative for convulsive states. The mother had passed through a short period of a situational depression following the patient's birth. The parents were divorced and the patient was an only child.

Physical Examination The physical examination showed a well-developed girl of twelve weighing 123 pounds and being 62 $\frac{3}{4}$ inches tall. No abnormalities of any kind were found in a detailed physical neurologic and mental examination. Laboratory studies showed the following:

Blood urea nitrogen 11.5 urea 24.6 uric acid 2.5 cholesterol 187.5 and 203 mg per cent calcium in serum 10.9 inorganic phosphorus 4.4 Wassermann negative. Complete blood count and differential normal.

Urine negative on 2 occasions.

Basal metabolism minus 18 per cent.

Spinal fluid clear, 5 lymphocytes total protein 28, globulin not increased colloid gold 0000000000 Wassermann negative in both alcoholic and cholesterolized antigens calcium 4.4 mg per 100 cc. Pressure and dynamics entirely normal.

Ophthalmologic study showed the visual fields, fundi and acuity normal in April and September 1937.

Intensive psychologic and psychometric tests were made during the early part of 1937.

The new Stanford Binet test gave an I.Q. of 107.

The Herring Binet test gave an I.Q. of 105.

The Arthur test gave 0.80.

There were no particularly significant reactions in the Jung association test.

The Pressey X-O test showed a possible emotional reaction to an unhappy social situation.

X rays of the skull made in March 1937 by Dr. C. G. Dyke, were reported as follows:

Single A.P. P.A. and lateral views of the skull show the vault to be of average thickness and not unusual in size or shape. There is no evidence of increased intracranial pressure and the sella turcica is normal in size and shape. There are multiple areas of calcification which vary in size from a few millimeters to close to a centimeter scattered on the surface and in the substance of the brain. The left hemisphere contains more of these shadows than the opposite side. The calcified areas tend to accumulate in the temporal, parietal, and frontal regions.

FIG 1, CASE 1 Lateral view showing multiple areas of intracerebral calcification

The central areas of the brain are practically not involved. The sphenoid and petrous ridges appear normal."

Impression Endarteritis calcificans cerebri

Skull x-rays of the father and mother of the patient were absolutely normal

Follow-up Course the patient has done extremely well in school since thyroid and phenobarbital medications were given. Her general attitude has improved, she is more alert, more social, in spite of her awareness that she is liable to have "a spell."

There was one severe attack in August, 1937, which was characterized chiefly by over-talkativeness and overactivity followed by a period of dizziness, unconsciousness, and violent jactitation. This phase lasted twenty minutes. Upon recovery, there was continued vomiting and a severe headache that lingered for about an hour. Upon being carried to bed, the patient fell asleep.

There have been several occasions during which the patient said her head felt queer, ached, and she was tired. She occasionally has some transitory difficulty in focusing on near-by objects, and on one occasion, she experienced sensations of colors like a rainbow that "moved around and suddenly disappeared."

It should be noted that medication by thyroid extract and small doses of phenobarbital was of much value in this case.

Summary This patient showed the following

FIG 2, CASE 1 A P view of skull showing multiple areas of intracerebral calcification

1 Multiple areas of calcification within both hemispheres of the brain

2 Convulsions (petit-mal, grand-mal, and epileptic equivalents)

3 Metabolic rate below normal

4 Scholastic difficulties (before medication)

5 Visual hallucinations (once)

6 Preservation of normal visual function

7 No cliniconeurologic signs

8 Normal laboratory studies of cerebrospinal fluid, blood, and urine.

Case 2—N I (29830) D D, white, schoolgirl, aged 16½ years, entered the Neurological Institute on February 9, 1937, with the chief complaints of poor vision, mental sluggishness, headaches, and convulsive seizures.

Present Illness The mother stated that the patient was a normal birth and normal in development until the age of three, when it was noticed that the child was unaware of movements about her and failed to grasp objects brought within view. Since then, the patient's vision had become progressively impaired so that at the present time she has remaining only moderate perception for light, color, and printed

words, and is barely able to recognize people about her.

The mother said that in comparison with other children, her daughter appeared retarded in speech and motor accomplishments. At the age of 16 months, the child fell and struck the left side of her head, and her mother believes that since that time, the patient has been sluggish both mentally and physically. However, there was no peculiar behavior disorder noticed following this slight trauma. As the patient became older, she appeared to be inferior to children of her own age and disliked educational subjects because she could not retain information. She preferred to do gymnastics because she could compete quite well with her companions in spite of her visual handicap.

The patient stated that she began to have headaches, located across the forehead and at times in both temporal regions, at the age of 13. These headaches were of a dull aching and throbbing character, lasting for six or more hours, accompanied by nausea and dizziness but without vomiting. They have occurred only in association with the menstrual periods. In addition, she noticed at various intervals faint streaks or flashes of red or blue light in either visual field which persisted for a few seconds and were relieved by closing the eyes. They were often noted prior to the onset of her headaches and became more frequent and profound at the time of the first convulsive attack.

Approximately ten months prior to her admission to the hospital, she experienced her first convulsive seizure. There was a general feeling of dizziness prior to the attack, followed by rigidity with unconsciousness, stertorous breathing, saliorrhea, biting of the tongue and generalized tonic and clonic movements, always with greater involvement of the right half of the body. This was followed by generalized headaches lasting one-half hour. There was no urinary or rectal incontinence. She had had five such attacks before her admission to the hospital and one preceded by remarkable streaks and flares of light. There were no petit mal or jacksonian episodes.

Her menstrual periods had been regular until a year ago when the duration of the flow became shortened and the interval period lengthened.

Past History. She had had chicken pox and diphtheria as a child with no neurologic complications.

Family History. There is an older sister and a younger brother who are well. No history of consanguinity, epilepsy, psychoses, or familial hereditary diseases of the central nervous system in either the maternal or paternal lineage.

Physical Examination. This revealed a fairly well nourished and developed white female of hypoplastic habitus weighing 104.5 pounds and being 151.5 cm. tall. The cranium was of the microcephalic type with a circumference of 49 cm. There were no abnormalities of the cardiovascular, respiratory, gastrointestinal or skeletal systems.

Neurologic Examination. This showed no abnormalities of gait or co-ordination. There was a marked tremor of coarse type on extension of the hands, with some athetoid posturing of the right hand. The deep reflexes were equal and very active; the superficial reflexes were normal except for the plantar response on the left. The grip of both hands was of good strength. There were no changes noted in the muscular system. Sensation was intact. There was a definite lag in the ability to move her fingers at command although she moved them promptly upon touch and was able to perform complex acts such as intertwining the fingers in normal or reversed manner.

The cranial nerves showed the following alterations: inequality of the pupils, the left being larger than the right, with good reaction to light; direct and indirect responses on accommodation and convergence could not be elicited due to nystagmus. The nystagmus was of a rolling, rhythmic, inco-ordinate type easily elicited when the patient moved her eyes in any direction. There was full excursion of ocular movements in all directions. These movements, however, could not be maintained due to the lack of power to fix the gaze. The palpebral fissures were equal.

The fundi were the seat of multiple areas of old choroideremia with pigmentary degeneration of the retina and optic atrophy. There were opacities of the vitreous. The arteries were reduced to mere threads, this being more noticeable in the left fundus. The discs were pale and there was no evidence of edema. The visual acuity averaged 4/200 in each eye. She was able to discern color. Due to the lack of central vision, examination of the visual fields could not be accomplished. Other cranial nerves were normal.

Mental examination showed a very responsive, suggestible individual with childlike behavior, perhaps the result of insecurity and inferiority. She was emotionally unstable, showed impairment of memory for recent and remote events and inability to do simple calculations. Given the Irwin-Hayes revision of the Binet-Simon tests standardized for blind subjects, she showed an intelligence quotient of 0.63. Laboratory findings were as follows:

FIG 1, CASE 2 Lateral view of skull Arrows point to calcified areas

Blood count Hb 88, color index 0.89, RBC 4,980,000, WBC 8,500, polynuclears 48, lymphocytes 50, eosinophiles 2, morphology, normal.

Blood chemistry urea N 13.6, uric acid 3.2, sugar 96, chlorides 515, calcium 10.1, phosphorus 3.9, cholesterol 132

Blood Wassermann negative.

Urinalysis turbid, amber, reaction acid, sp gr 1.027, albumin, a faint trace, sugar negative, pus cells, many

Spinal fluid cells 0, globulin 0, protein 36, gold curve 1110000000, Wassermann negative.

Basal metabolism BMR- minus 15

X-ray stereoscopic views of the skull showed the bones of the vault somewhat thickened and the size of the vault smaller than normal. The sella turcica was normal in size and appearance. Multiple areas of calcification were seen within the cerebrum, several areas being in the left parietal region, a single area in the right frontal, and one in the right occipital region.

Encephalographic studies performed on the third and ninth day after admission revealed normal cerebral structures.

Course in hospital The patient's general course in the hospital was uneventful. She exhibited childish attitudes and cried upon the least provocation. No convulsive seizures occurred during her stay, and she was discharged 11 days after admission, unimproved. The patient was seen again in April 1, 1937, and on

FIG 2, CASE 2 A.P. view of skull Arrow points to areas of calcification within the brain substance.

May 6, 1937, and during the interval, had had only one seizure. Her general mental attitude and behavior remained the same. Her school-work is generally poor and she has difficulty in her association with other children.

Summary This patient showed the following

- 1 Multiple areas of calcification within the brain substance.
- 2 Chorioretinitis, optic atrophy, and nystagmus
- 3 Convulsive attacks of the grand mal type, preceded by visual hallucinations of "flares and streaks of light"
- 4 Mental deficiency
- 5 Definite but moderately low basal metabolism
- 6 Normal encephalograms on two occasions

Case 3—M N, a white adult, married, female, aged 39, was admitted to the Bellevue Hospital, Neurologic Department, on April 9, 1936, with the complaints of poor vision, generalized convulsive seizures, and right temporal head aches, of seven years' duration.

Present Illness This patient was first seen

FIG 1 CASE 3 Lateral view of skull which shows the intracerebral areas of calcification.

FIG 2 CASE 3 Ventriculogram showing areas of calcification and moderate dilatation of ventricular system

in the Neurological Outpatient Department in June, 1931 at which time she told of having had generalized convulsive seizures for the preceding two years, during which everything would turn black, and my head would turn to the right side.' She would be unconscious for 15 minutes and occasionally bite her tongue. She was given sedative medication and followed in the O.P.D. for several years and preceding this last admission to the hospital, she complained of pain in the right temporal region. Occasionally her convulsions started with left sided clonic twitches. Her fits occurred twice weekly. In addition she has noticed progressive difficulty with vision which extended over a period of 7 or 8 years.

Past History Birth and early development were normal. Appendectomy at the age of 24, operation for abdominal adhesions at 27 acute, purulent otitis media, which subsided completely with conservative treatment at the age of 38.

Physical Examination A well-nourished adult female, weighing 140 pounds and 5 feet 8 inches tall, of asthenic habitus cranium of normal size and shape no abnormalities of the cardiovascular respiratory gastrointestinal muscular or skeletal systems. Blood pressure, 120/74.

Neurologic Examination Cranial nerves—no defect in smell. There is bilateral atrophic choroiditis with mottled black pigment de-

position bilateral optic atrophy and associated visual defect. The left pupil was irregular but both reacted to light and on accommodation. There was slight limitation of left lateral gaze with the left eye. Otherwise the cranial nerves were normal.

Motor power—good in all extremities, no focal atrophies or fibrillations co-ordination normal of station, limb and gait reflexes deep—all present and equal superficial—all normal no sphincteric difficulty sensation entirely normal to all forms of stimuli speech normal.

Mental status patient was slow and child like in responding to questions speech was not spontaneous but apt to be only in response to questions. There was no distractibility scattering or blocking mood statement 'feel all right, not sad or happy' no paranoid trends, compulsions delusions or hallucinations.

Orientation and memory were poor especially memory for recent events. Retention, poor she could remember only 1 or 3 objects after 5 minutes could not repeat 4 digits backwards. Calculations, poor.

General information—poor with a tendency to talk in general terms or circumlocution or ramble when asked specific questions. The patient had insight into her disabilities and illness. Laboratory data blood count Hb 60 per cent RBC 4 000 000 normal white count and differential smear blood chemistry normal.

FIG 3, CASE 3 Ventriculogram, A P view

sugar, urea nitrogen, uric acid, chlorides, calcium, phosphorus, and cholesterol, blood Wassermann negative, urinalysis entirely normal with specific gravity of 1.020, spinal fluid pressure and dynamics normal, clear, colorless, 5 mononuclears per cu mm, total protein 60 mg per cent, colloidal gold 0011000000, Wassermann, negative, basal metabolism minus 13 per cent

X-rays of the skull showed scattered discrete foci of calcification measuring 1 to 3 mm in diameter, chiefly located in both occipital lobes, also present in both frontal and parietal lobes

Ventriculograms showed considerable symmetrical dilatation of the entire ventricular system with no tendency to displacement to either side

Course in Hospital Uneventful Her convulsive seizures were controlled by Luminal medication, $\frac{1}{2}$ gr three times a day She was also given vitamin, liver extract, and iron therapy, to alleviate her anemia Mentally, she remained dull, at times overtalkative, but had no periods of confusion aside from those associated with her postconvulsive state

Summary This patient showed the following (1) multiple small areas of calcification throughout the brain, especially in the occipital lobes, (2) Bilateral chorioretinitis, (3) Generalized convulsive seizures, starting with focal clonic seizures in the left leg, (4) Mental signs of an

organic (anergasic) syndrome, (5) Evidence of moderate symmetrical internal hydrocephalus

Summary

Three cases are described wherein multiple areas of intracerebral calcification were associated with paroxysmal convulsive disorders The subjects were 12, 16, and 39 years of age All had low basal metabolic readings Two of our patients showed atrophic chorioretinitis, with optic atrophy We believe these cases represent a clinical group in which several of the outstanding phenomena are due to faulty calcium metabolism

PANHISTERECTOMY

A Study Based on 2,773 Consecutive Hysterectomies

EDWARD P. McDONALD M.D., F.A.C.S., Albany, New York

(From the Gynecologic Department of the Albany Hospital and the Albany Medical College)

THE primary object of this paper is to present to this section the conclusions we have drawn from a study of 2,773 consecutive hysterectomies. The secondary object is to place our clinic on record as advocating complete, total, or pan hysterectomy as a routine operative procedure of choice in benign conditions of the uterus.

Many are of the opinion that statistics mean but little and probably there is some justification for the belief. Faulkner, in presenting 1,554 cases of hysterectomy, states "If there is any value in figures it is in those from a large series of consecutive operations, done on young and old, good cases and bad, by experienced and inexperienced operators, that is, hysterectomy as it is, not hysterectomy as it might be." This we have done.

These operations were all performed in the Albany Hospital on the gynecologic service by five members of the gynecologic staff and five resident gynecologists, over a period of ten years, from January 1, 1926, to December 31, 1935. This study represents all of our cases over this period, good risks and poor ones, done principally by staff members, but with a large percentage of the service cases performed by resident gynecologists. The operations done by the residents were under the direct supervision of one of the staff members.

Of the total number of operations performed there were but 145 or 5.52 per cent of subtotal, incomplete, or supravaginal hysterectomies, with a mortality of 2.75 per cent, whereas, 2,628 or 94.48 per cent were total, complete, or pan hysterectomies, with a mortality of 1.02 per cent. The general operative mor-

tality of all cases, total and subtotal, was 1.11 per cent.

We are interested in presenting our results in support of our contention that panhysterectomy is a justifiable routine in benign conditions of the uterus. Of the 2,773 cases, 274 presented malignant disease, of these 11 died with an operative mortality of 4.01 per cent. There were 2,499 in benign conditions of the uterus, with 20 deaths and an operative mortality of 0.80 per cent. Of the 2,499 cases of benign conditions of the uterus, 2,355 had complete hysterectomies with 16 deaths and an operative mortality of 0.67 per cent.

The trend among American gynecologists seems to be more and more toward complete hysterectomy. Until recent years there were few clinics doing total hysterectomies except in carefully selected cases, such as carcinoma of the body of the uterus or extensive laceration of the cervix, and the high operative mortality was used as an argument against complete removal in benign conditions. Time was spent in amputation, repair, or cauterization of the cervix preceding the supravaginal removal of the uterus. In other words, time was spent so that the diseased cervix could be preserved, rather than spending the time in its removal and the elimination of its potential dangers. Men trusted to their gross observation of a cervix in determining a "normal" from a "diseased" organ. The fact is, that a uterus sufficiently diseased to warrant its removal seldom if ever contains a "normal cervix." The cervix left *in situ* is always potentially dangerous, it is always a liability to a patient, never an asset. Cutting across a diseased organ with its

CHART II CAUSES OF DEATH

| SUPRAVAGINAL HYSTERECTOMY | |
|---|---|
| Operation performed for | Cause of death |
| 1 Acute and chronic pelvic inflammatory disease | General toxemia—44 years of age |
| 2 Cesarean section | Pulmonary embolus—38 years of age |
| 3 Myomatous uterus | Myocardial insufficiency—63 years of age |
| 4 Carcinoma of ovary | Bronchopneumonia—36 years of age |
| PANHYSTERECTOMY | |
| Operation performed for | Cause of death |
| 1 Carcinoma of body of uterus | Myocardial insufficiency 2 cases, 62 years of age |
| 2 Carcinoma of body of uterus | With metastasis 3 cases 60 46, 66 years of age |
| 3 Carcinoma of body of uterus | Bronchopneumonia and paralytic ileus, 55 years of age |
| 4 Carcinoma of body of uterus | Pulmonary embolus 67 years of age |
| 5 Carcinoma of body of uterus | Paralytic ileus 69 years of age |
| 6 Carcinoma of body of uterus | Paratyphoid infection 65 years of age |
| 7 Carcinoma of tube | Metastasis 60 years of age |
| 8 Leiomyomatous uterus | Bronchopneumonia 3 cases 45 40 41 years of age |

Richardson, in one of his papers, gives good advice "Complete mastery of a satisfactory technic for total removal of the uterus by both the abdominal and the vaginal routes is a minimum standard of operative skill that every gynecologist should exact of himself as early in his career as the circumstances of his period of apprenticeship will permit. Otherwise, he will find himself frequently confronted with situations in which the best interests of his patients cannot be served because of his lack of proficiency in executing the operation that is best adapted to their needs." I am certain that in the hands of untrained men, the minor, but often

times, major, operation of appendectomy might carry with it an alarming mortality

The danger of injury to surrounding structures is in direct proportion to the care, skill, and ability of the operator. I do not mean to infer that all operative accidents are avoidable. The size of the patient, the depth of the pelvis, the lack of proper exposure, and the type of pelvic disease, are all factors which predispose to accident.

In our series of cases, 2 deaths are directly due to just such accidents. One died of peritonitis. At autopsy, a small perforation was found in the anterior rectal wall. It was a case of pelvic in

flammatory disease with large, adherent, bilateral tube-ovarian masses. I am sure that if we did then what we do now in all cases where there is even a possibility of bowel injury, that is, fill the rectum with water before closing the abdomen, the injury would have been discovered and repaired, and possibly the patient's life would have been saved. The second case was an injury to the fundus of the bladder sustained during the difficult removal of a leiomyomatous uterus. The injury was repaired at the time, but the patient died of peritonitis and septicemia. However, one must keep in mind that exactly the same accidents could happen during the procedure of supravaginal hysterectomy.

In panhysterectomy, where the bladder is freed from the cervix, I believe the chance of injury to it is less than in supravaginal hysterectomy. Injury to the ureters can frequently be avoided by a thorough knowledge of the pelvic anatomy and the ligation of the uterine arteries close to the cervix. If there is any question, locating the ureters is no problem. Injury to the rectum is possible in both procedures, but probably more so in complete removal. We do not fear this in the average case. Where there is any question of injury, we test the large bowel as stated above.

There is no sound anatomic reason to support the statement that "the cervix left *in situ* supports the vaginal vault." I have solicited the opinion of anatomists on this point and they are not willing to subscribe to it. We do know, however, that the cervix left in place frequently serves as an excellent runner for the bladder to slide down upon, and that varying degrees of bladder prolapse are not uncommonly found after supravaginal hysterectomy.

We do not feel that removal of the cervix shortens the vaginal canal. Correct utilization of the round ligaments will more often lengthen the canal. It is difficult to see how the removal of a large lacerated cervix is going to lessen the capacity or length of a vaginal canal. The cervix is potentially dangerous, both from the standpoint of possible malig-

nancy and of the more common finding, chronic and acute infection, specific and nonspecific, with its distressing vaginal discharge. Chronic infection has long been accepted as a predisposing factor in carcinoma. The disadvantages of a remaining cervix are obvious, the advantages we have yet to find.

Cancer of the cervical stump does occur, perhaps more often than we suppose. In a review of the literature, von Graff found that in 4,269 cases of cancer of the cervix, 4.1 per cent present were stump cancers. The percentage usually given is between 2 and 6 per cent. Perhaps 3 or 4 per cent comes closer to the real figure.

The association of cervical cancer with leiomyomata deserves careful thought. It has been stated that the cervix in 3 to 5 per cent of fibroid tumors has or develops malignancy, and that two-thirds of all stump cancers follow supravaginal hysterectomy for uterine tumors. And yet, some believe that a leiomyomatous uterus in a nulliparous woman is an indication for supravaginal hysterectomy. The feeling that cervical cancer is rare in the nulliparous woman has long ago been proved incorrect.

Coring or cauterization of the endocervix is no guarantee against carcinoma. The fact is the squamous portion of the cervix is the most frequent sight of the growth (von Graff, 80 per cent). As high as 14 per cent cures have been reported in cases of stump cancer which developed in less than three years after the supravaginal hysterectomy. We feel that the true progress in malignant disease should follow the road of prophylaxis rather than that of treatment, at least until the etiologic factor is established.

I am not unmindful of the fact that if panhysterectomy is done promiscuously by those untrained in pelvic surgery, the mortality will be high. Certainly it is not the object of this paper to advocate the acceptance of this procedure by men who do but an occasional hysterectomy, neither is it intended to give the impression that a supravaginal hysterectomy in selected cases is wrong. The operator must select the type of operation which he

feels is to the best interest of the patient and proceed accordingly. We feel that complete hysterectomy is the operative procedure of choice, not only in malignant, but also in benign, conditions of the uterus.

Conclusions

1 The report of a study of 2,773 consecutive hysterectomies, 94.4 per cent of which were total hysterectomies.

2 Cervical stump cancer is not as rare as it was formerly supposed to be.

3 A cervical stump is a menace to the individual both from the standpoint of malignancy and of infection. It is a liability, never an asset.

4 In the hands of a competent operator, we unhesitatingly recommend total, complete, or panhysterectomy as the operative procedure of choice.

Discussion

Dr. Frederick C. Holden, New York.—We have just listened to a very interesting paper on the operative results of 2,628 complete hysterectomies done by five well trained gynecologists and five residents operating under their direction during a ten year period from 1920 to 1935.

Of these cases 274 were done for malignant diseases with an operative mortality of 4.01 per cent. In 2,355 complete hysterectomies were done for nonmalignant pathology with an operative mortality of 0.67 per cent. I agree with Dr. McDonald that the trend among American gynecologists seems to be more toward complete hysterectomy. It goes without saying that a retained cervix may at some time become malignant, but Dickinson and I have yet to see carcinoma develop in a cervix whose pathology we have cleared up with the electrocautery as we use it.

I take exception to Dr. McDonald's statement that complete hysterectomy does not shorten the vagina. Given a nulliparous woman with a short vagina complete hysterectomy will increase the possibility of further shortening with a resultant incurable dyspareunia. Dr. McDonald makes the statement we cannot subscribe to the belief that panhysterectomy carries with it

an increased mortality. This statement is true only when the operation is done by as competent a group as the gynecologists of the Albany Hospital who have perfected their technique by doing a tremendous number of such cases. Even in the hands of most competent operators the morbidity and mortality are undoubtedly greater in the panhysterectomy than in the supracervical hysterectomy. In this connection it is interesting to note that in 1927 of the 149 complete hysterectomies done the mortality was 2.34 per cent. Eight years afterward in 1934 372 complete hysterectomies were done by this same group with a mortality of 0.80 per cent—two-thirds less. Two thousand six hundred and twenty-eight complete hysterectomies in ten years is a very large number ranging from 130 in 1920 to 372 in 1934. Only the same staff operating such a very large number of cases could present results as good as these. However there are definite indications for supra vaginal hysterectomy and for complete hysterectomy. I therefore cannot subscribe to 94.5 per cent choice of complete hysterectomy as a routine procedure.

Will Dr. McDonald please tell us what is his preoperative preparation? Also given a woman with an adipose abdominal wall and a deep pelvis does Dr. McDonald free the cervical mucous membrane *per vaginam* first to facilitate the subsequent operative procedure above?

In reading over the paper I was unable to find any mention made of ureteral injuries and only one case each of injury to bladder and rectum. The use of the 'internal hot water bag' of Dr. John Clarke to determine whether or not there has been any bowel injury is an excellent plan as it definitely will indicate if the bowel has been injured and if so this can be repaired before abdominal closure. I recommend this procedure highly.

Murphy of the Woman's Hospital reported that during the last eight years 438 complete hysterectomies were done at this hospital with 3 vesicovaginal fistulas resulting. During this same period, 1,229 supracervical hysterectomies were done. Urinary infections occurred three times more frequently following complete hysterectomy and ureteral and bladder injuries occurred ten times more often in the total hysterectomy group. These are figures from an excellent gynecologic service.

I do not think it is unfair to say that, if all hysterectomies done were of the complete type the total death rate would be greater compared with what it is now with supracervical hysterectomies plus subsequent cancer deaths resulting from the retained cervix. If the cervix had

proper postoperative care, these cancer deaths could undoubtedly be greatly reduced

In closing I must offer my hearty congratulations to the Albany Hospital group who have so perfected their technic as to reduce their operative mortality—the total hysterectomy group of 2,628 consecutive cases to 1.11 per cent, and that they are able to report operative injury only once each to bladder and rectum, no ureteral injuries, and no vesicovaginal fistulas. I do not know of any other clinic able to report such excellent results.

I trust this paper will not be the cause of an increased operative mortality by other groups not so well trained, but we all should be inspired to emulate McDonald and his confreres in their perfection of the operative technic of complete hysterectomies.

Dr Erwin von Graff, *New York City*—As a pupil of the late Ernst Wertheim, I have always been in favor of the total hysterectomy and advocated it as the procedure of choice.

The main reason for this attitude has been the appalling number of stump cancers I have observed, both in Vienna and in the State of Iowa, with its unusually high rate of malignant tumors. Eight per cent of all the cervical cancers had developed on cervical stumps following subtotal hysterectomies.

By the most efficient combined treatment with operation and irradiation, we are able to cure

only 24 per cent of cervical cancers. The elimination of an added 8 per cent of stump cancers therefore constitutes an important gain and deserves serious consideration.

As to Dr F C Holden's remark concerning the possibility of preventing the development of cancer by proper treatment of the cervical stump, I must report that there were 37 cases among the material I published five years ago, in which cancer appeared in spite of coning out, plastic repair, carbolicization cautery, and application of radium. Technical difficulties in obese women can, in most instances, be circumvented by the vaginal approach.

My own operative results, with a mortality of 1.4 per cent in 480 abdominal total hysterectomies, are not as good as those reported by Dr McDonald. In spite of this, the potential danger of malignancy and the many advantages stressed by the speaker have convinced me once more of the superiority of the total over the subtotal hysterectomy.

The subtotal has, and always will have, its place in selected cases. I certainly do not recommend the more radical procedure in the hands of unskilled operators. However, I feel very strongly that any pelvic surgeon who accepts the responsibility of performing a subtotal should be sufficiently competent and experienced to perform a total hysterectomy if the necessity arises.

A RECORD YEAR IN SOCIAL HYGIENE

New York City has taken a place in the forefront of the nationwide effort to reduce syphilis and gonorrhea, says the report of the city Bureau of Social Hygiene. The individuals treated in 1938 totalled 31,109, an increase of 41 per cent over 1937. Treatments administered totalled 501,265, an increase of 24 per cent over 1937. The decrease in the number of treatments per patient has been brought about by consultation and improved treatment, and represents increased clinical efficiency. Delinquent cases are followed up by social service workers, in 1938, 16,712 lapsed cases were returned to treatment. In addition, 8,308 contacts and 804 named sources of infection were brought in for examination, of these, 11.5 per cent and 20.5 per cent, respectively, were found diseased.

To aid private physicians in discovering, treating, and controlling syphilis among their patients, free blood tests, darkfield examinations, smears and intradermal tests for lymphogranuloma inguinale are performed. The services of medical

and nurse epidemiologists and investigators are available to private physicians for consultation, to follow up lapsed cases, and to locate sources of infection and contacts. During 1938, 1,009 physicians were visited and interviewed.

To enable as many patients as possible to continue under the care of private physicians, 529,500 doses of drugs for the treatment of syphilis were distributed during 1938 to private physicians and hospitals. Of these, 426,130 or 80 per cent were distributed to private physicians and the remainder to hospitals. The amount distributed to private physicians is equivalent to the 439,620 syphilis treatments given by Health Department clinics during 1938.

Private physicians have been co-operating with the Bureau in its effort to have syphilis and gonorrhea reported properly. During 1938, 37,077 cases of syphilis and 12,935 cases of gonorrhea were reported. This is over four times as many as were reported in 1937. Private physicians reported 40 per cent of the total cases.

DOSAGE SPECIFICATIONS IN X-RAY THERAPY

EDITH H. QUIMBY, New York City

(Associate Physicist Memorial Hospital)

IN GENERAL, when a new form of therapy is discovered, there is a period during its gradual acceptance when the expression of its dosage undergoes development. Various schemes or methods may be suggested, tried out, and discarded. Finally one is adopted, becomes familiar, its use becomes routine, and precautions necessary to its correct employment are taken automatically.

The expression of dosage in radiation therapy is still in the developmental stage, although during the past year steps have been taken to stabilize it by the adoption of a satisfactory unit.

Time does not permit any historical consideration of the development of various methods of dosage specification, the purpose of the present paper is to discuss the unit recently adopted, point out the precautions which must be observed in its use, and note its limitations.

Almost ten years ago, at the meeting of the Second International Congress of Radiology, the *roentgen* was adopted as the unit of quantity of x rays¹. As defined at that time, this unit could be used correctly only for the measurement in air of quantity of x rays, over a limited range of quality. During the next nine years, efforts were made continually to extend its use both to higher voltage x rays and gamma rays in air, and to all qualities of radiation in tissue. Finally, at the Fifth International Congress, in 1937, the definition of the roentgen was changed to facilitate its use in these aspects of the problem². The roentgen is now defined as that quantity of radiation whose corpuscular emission produces in 0.001293 Gm. of dry air one electrostatic unit of

charge of either sign. Nothing is said about the manner in which the measurement shall be made, the necessary precautions, or the limitations of the results. Such measurement, for hard radiations, and for radiations in tissues, is one of the problems occupying radiologic physicists at the present time. It is being necessary to develop special types of ionization chambers to be sure that all the ions correctly included are measured, and that no extraneous ones are introduced. The development of correct measuring methods is the problem of the physicist rather than that of the practicing radiologist, accordingly, a discussion of this aspect of the problem is hardly desirable at the present time.

Assuming that a correct measurement is possible, let us consider what is actually meant when one speaks of air dose or of tissue dose in terms of roentgens. Throughout any beam of x rays, the matter traversed is being ionized. It is assumed that biologic reactions are a direct consequence of this ionization, and that a definite relation exists between the amount of ionization and the effect to be expected. Ionization in the tissues cannot be measured directly at the present time, however, under proper conditions the ionization in an extremely small volume of air in the midst of tissue can be determined. Since the composition of air and that of tissue are quite similar, it may be assumed for dosage purposes that equal ionization is produced in equal masses of air and of tissue.[†]

For the calibration of the x ray tube, on which rests the determination of the dose in air in any particular case, a particular small volume of air is selected, in the center of the beam and at a definite distance from the target, and the number

* 0.001293 Gm. is the mass of 1 cc. of dry air under standard conditions.

† Experiments are being conducted to determine the extent of the differences between ionization in air and in gases having the same composition as tissue.

TABLE I—NUMBER OF ROENTGENS DELIVERED AT CENTER OF VARIOUS SKIN FIELDS FOR 100 ROENTGENS IN AIR

| VOLTAGE KV (CONST. POT.) | FILTER MM | HALF VALUE LAYER MM. CU | AREA OF FIELD, SQ CM | | | | | | |
|-----------------------------|--------------|-------------------------------|----------------------|-----|--------------------------------|-----|-----|-----|-----|
| | | | 5 | 10 | 25 No of r for 100 r in Air | 50 | 100 | 200 | 400 |
| 100 | 0 | 0.035 | 110 | 114 | 117 | 121 | 124 | 126 | 128 |
| 150 | 5 Al | 0.3 | 114 | 118 | 124 | 130 | 134 | 140 | 147 |
| 200 | 0.5 Cu | 1.0 | 114 | 118 | 124 | 130 | 136 | 143 | 149 |
| 200 | 2.0 Cu | 2.0 | 109 | 112 | 117 | 121 | 126 | 131 | 136 |

of ions produced in it is measured. The weight of this small volume of air can be found from standard tables, and the number of ions per 0.001293 Gm determined. One electrostatic unit of charge consists of 4.19×10^{10} ions, that is, they represent the effect in this amount of air of one roentgen. The number of roentgens thus determined is spoken of as the output of the tube.

If the attention be concentrated on a minute volume of air in the x-ray beam, which may be taken as representative of a minute volume of tissue, the discussion of the meaning of dosage specifications will be facilitated. Consider, first, this volume in air, as the calibration is made. Every roentgen passing through it produces ions in it at the rate specified by the calibration; this is the result of the air dose. If, now, a patient is brought directly under this small volume of air, the ionization in it is markedly increased, because, in addition to the primary beam, there is now radiation scattered back by the body of the patient. The amount of this scatter will depend, among other things, on the size of the irradiated area. It is well known that, whereas the size of the diaphragm in general has little or no influence on the ionization at the center of the beam in air, the size of the field is very important in a consideration of back-scatter. With a small one, very little of the patient's body contributes to the effect, so that the increase in ionization will be slight, whereas with a large one it will be greater. Actually, with a very large field it may amount to more than 50 per cent of that caused by the primary beam. It is the sum of the primary and back-scattered radiation, represented by this total ionization, which is effective in the patient's skin in the region repre-

sented by the minute volume of air under consideration.

It is evident that if only a thin part of the body is irradiated—a hand, for instance—less back-scatter will result, for any size of field, than for a thick part.

Moreover, it is true that different qualities of radiation are scattered differently. The maximum back-scatter is obtained with radiation having a half value layer of about half a millimeter of copper; this is obtained at about 150 kv and 4 or 5 mm of aluminium filter (so-called "intermediate voltage"), for either harder or softer radiation it becomes progressively less.

From these considerations it is evident that, whereas a dose of radiation in air can be determined simply from the calibration of the machine, the dose effective on the surface of the body can be found only when the back-scatter factor is known for the proper quality of radiation, size of field, and thickness of underlying material. Of course, if a properly designed ionization chamber could be put on the skin at the center of the field, the number of roentgens passing through that region could be read directly. Unfortunately, most of the available small chambers have wall effects and other peculiarities which make them inaccurate. However, with the extensive tables which are now available, it is a simple matter to determine the skin dose when the air dose and treatment details are known. Table I shows the skin dose, for 100 roentgens in air, for four qualities of radiation commonly used, for a wide range of fields, assuming enough underlying material to assure the maximum back-scatter. Comprehensive tables of this sort are published elsewhere.⁴

It should be stated that distance from

TABLE II—NUMBER OF ROENTGENS DELIVERED AT VARIOUS DEPTHS IN FIELDS OF VARIOUS SIZES, FOR 100 ROENTGENS IN AIR

| DEPTH CM. | 200 KV (CONST. POT.) 0.5 MM. CU FILTER. H V L. 10 MM. CU | | | | | | | | | | | |

the source (at least within the limits used in therapy) has no effect on the relation of skin dose to air dose. Of course the distance affects the amount of radiation reaching a given point in a given time, the farther away the source the longer it takes to deliver a given amount of radiation. But for the same irradiated area and the same quality of radiation, substantially the same percentage is scattered back.

In the measurement of dosage within the body, the number of ions produced per 0.001293 Gm in a vanishingly small volume of air in the location under consideration must be determined, in order to obtain what at present appears to be the most direct measure of tissue dose. Obviously in general even if the skin dose could be obtained by direct measurement on the patient, the depth dose could not, since only rarely can the measuring instrument be introduced into the body. However, with suitable chambers and phantoms it is possible to make measurements which can be used to express the tissue dose under any given set of conditions. Table II shows the number of roentgens delivered at various depths in fields of various sizes, per 100 roentgens in air, for radiation at 200 kv, 0.5 mm. copper filter, half value layer 1 mm copper, for 50 and 70 cm. target skin distances. Of course the values for zero depth are the same as those for the skin dose in Table I, for this quality of radiation.

Although the distance makes no difference in the relation of the skin dose to the air dose, it does make a considerable difference in the relation of the depth dose

to either the skin or the air dose. This is purely a matter of geometry, for this reason, when depth doses have been found for one distance, they may be calculated for others, within reasonable limits.

It is important that measurements used for determining tissue doses shall have been made in phantoms comparable in size with the part of the body undergoing treatment. The use of data obtained with large phantoms to specify doses in smaller portions of the body, such as the limbs or neck, may introduce errors because of the difference in the actual amounts of scattering material in the two cases. Tables will be available in the near future for depth doses for various fields, distances, qualities of radiation, and parts of the body.

Consider now what is really meant when the dose of radiation delivered to the patient is expressed in roentgens, both on the skin and in the tumor. It is the amount of radiation passing through the region which is specified, it is, however, the resulting ionization which is implicitly thought of. For example, suppose that a lesion is so situated that it can be irradiated through an anterior and a lateral field, being 10 cm. below the surface in the former and 7 cm. in the latter case. Using 200 kv, 0.5 mm copper, and a 50 cm distance, 1,000 r measured in air are given to a 100 sq cm anterior port and to a 50 sq cm. lateral one. The amount of radiation effective on the skin can be determined from Table I, 1,360 r for the larger, and 1,300 r for the smaller field. This means that ionization is produced in these two regions as already dis-

cussed As the two beams pass through the body, each produces ions throughout its path—the manifestation of the depth dose This becomes less per unit volume as the depth increases, because of the absorption and scattering of the radiation as well as because of the geometric spreading of the rays For any depth in either field, in this particular case, the depth dose can be determined from Table II In the region of the tumor, where the beams cross, the ionization produced by each is independent of the other, and the total effect is due to their sum In this instance, at the center of the tumor, the depth dose is 410 r from the larger beam and 530 r from the smaller (the depth for this latter being less), 940 r altogether

It is evident that, while it is correct to add the doses to the tumor from two (or more) different ports, and state the tumor dose as the total, it is not correct to add the doses to all the skin fields and state this as the dose administered to the patient As a matter of fact, the main reason for stating the skin dose is to give some idea of the skin reaction to be expected This cannot be had from a mere knowledge of the total number of roentgens, it is necessary to know also the number of ports and the division of the roentgens among them One would not say that a patient received four erythema doses to his skin, if he actually received one erythema dose to each of four fields, the statement of total skin dose in roentgens has just as little meaning

It has been customary in this country to express tissue doses in terms of some form of erythema dose The transition to roentgens is not difficult, but there are some errors which must be avoided The relation between the two, for the standard threshold erythema dose and a particular field and quality of radiation, is given in Table III One threshold erythema dose, *in air*, for the specified field, is 500 r, this means 680 r on the skin (36 per cent back-scatter) Of this skin dose, percentage depth doses can be taken as usual But percentage depth dose, based on 100 per cent at the surface, cannot, of course, be applied to the roentgen dose as specified

TABLE III —RELATION BETWEEN THRESHOLD ERYTHEMA DOSES AND ROENTGENS
200 Kv 0.5 MM. Cu FILTER. 10 MM Cu HVL.
100 Sq Cm FIELD 50 CM TARGET-SKIN DISTANCE.
1 T E D = 500 ROENTGENS IN AIR

| DEPTH CM | NUMBER OF ROENTGENS TO TISSUE | PERCENTAGE OF AIR DOSE | PERCENTAGE OF SURFACE DOSE | T E D |
|-------------|--|------------------------------|-------------------------------------|-------|
| 0 | 680 | 136 | 100 | 1 |
| 1 | 665 | 133 | 98 | 0.98 |
| 2 | 605 | 121 | 89 | 0.89 |
| 3 | 535 | 107 | 79 | 0.79 |
| 5 | 400 | 82 | 60 | 0.60 |
| 7 | 305 | 61 | 45 | 0.45 |
| 10 | 205 | 41 | 30 | 0.30 |
| 15 | 110 | 22 | 16 | 0.16 |

in air On the other hand, if the tissue dose has been worked out in roentgens from the start, and it is desired to translate this into erythema doses for the sake of comparison with old data, it must be remembered that *the number of roentgens to be taken for the erythema dose is that including back-scatter, not that in air* In other words, to translate the roentgen doses in Table II into threshold erythema doses, for the 100 sq cm field, the erythema dose is 680 r, not 500 r, for this particular quality of radiation (This applies strictly only to radiation delivered at a fairly high rate and in one sitting If the treatment is protracted or fractionated, the number of roentgens per actual erythema dose, whether specified in air or on the skin, will be greater However, in practice the total radiation delivered is often specified in terms of a total number of erythema doses, no allowance being made for a time factor In such a case it is most important to state the magnitudes of the individual doses and the intervals between them)

In any complete scheme of specification of radiation dosage, it is necessary to state the quality as well as the quantity of the radiation This is conventionally done by the half value layer of the radiation in some convenient metal—aluminum, copper, or tin, depending on the voltage range Such measurements are, of necessity, made on the primary beam in air

If the quality of the radiation had no influence on the biologic result to be expected, it could be ignored, a given num-

ber of ions produced in a certain region would produce the same effect, regardless of the wave length of the rays producing them. In such a case, if a lesion were treated with a combination of soft x rays and gamma rays, it would be legitimate to express the total dose by a direct addition of the numbers of roentgens in the two cases. However it is not at all certain that this is the case in general, and it is well known that in some instances, especially in the skin reaction, the effect produced by a given dose is dependent on the quality of the primary beam.

As the radiation passes through the body, its average quality changes, it becomes softer. As energy from the rays is used up in producing ionization, that remaining becomes steadily less, on the average. Even if the beam is fairly homogeneous as it enters the body, it becomes more and more heterogeneous as its component rays undergo varying amounts of absorption and scattering. It is evident, therefore, that if a lesion is at quite different distances from various skin portals, the quality of radiation it receives may be different for different beams, even if the initial qualities were the same. For deep-seated tumors this difference is probably not enough to be significant. There is, however, one case in which attention might well be paid to it, and that is in connection with the *exit dose*. This is the amount of radiation delivered on any skin surface by a beam which has previously traversed the body, for example, the amount delivered on one side of the neck by the beam which was incident on the other side. With penetrating radiation and small body thickness, this contribution may be considerable. It consists of radiation definitely softer than the primary beam, and hence more effective in producing skin reaction. Simple addition of the numbers of roentgens in the two parts of the dose on this skin field might give a false idea of the reaction to be expected. The portion which is due to the exit dose may exert an unduly large influence. This is one good reason for so arranging the fields (when possible) that the

port of exit does not coincide with the port of entry of another beam.

In addition to all these physical considerations, it must not be lost sight of that certain biologic considerations are significant. The intrinsic factors of relative sensitivity of various organs and various types of diseased tissue, as well as of the whole individual, are matters for the radiologist to consider in any plan of treatment. The extrinsic factors concerned with the rate of administration of the radiation, that is, the fractionation and the protraction, play an important part. In order to specify the biologically effective dose over a period of time, some means must be found to express the net biologic effect, allowing for tissue recovery. This is not a simple problem, nor can results obtained for any one organ or tissue be applied to any other without further investigation. Experimental work on laboratory biologic media has no direct application to human reactions. Observations on the behavior of the human skin form the basis for most of the systematic study of recovery up to the present time. Early efforts along these lines were directed toward the finding of a constant daily recovery factor, which was dependent on the quality of the radiation. Later it was shown experimentally that, during a series of treatments, much greater recovery takes place in the twenty-four hours following the first one than in any subsequent equal period. Previously unirradiated skin combats the action of the rays more strongly than that which has undergone any degree whatever of radiation damage. During a course of repeated irradiations, recovery on successive days is progressively less until a point is reached (if the treatment is carried on long enough) after which damage is permanent. There are, however, no very definite data on the rate of recovery of other tissues. Probably under certain conditions each tissue has its own recovery rate.

In some cases the accumulated dose in the skin can be satisfactorily calculated on the basis of published tables, but this

work is still incomplete No data are as yet available for determining the accumulation of dosage in any other human tissues

Since the method of dosage specification in radiation therapy is still definitely in the developmental stage, it should be urged upon all radiologists in recording their treatments, to note all possible factors, both physical and biologic With these available, the data will be useful at any future time, even though units may still undergo considerable change

Discussion

Dr Harriet C. McIntosh, New York City—While current schemes of dosage administration might go on about as well measured in percentages as in roentgens, the enlarged and clarified picture of what we are actually doing, as illustrated by this paper, has certainly put us another good step forward in our attack on the dosage problem, and correspondingly narrowed the No Man's Land that still exists It is striking to realize how much of this mapping and surveying of uncharted territory Mrs Quimby herself is responsible for, but there is still, as we know, much undiscovered or incompletely surveyed Mrs Quimby's contribution today is based on single doses, or closely massed fractions What about the values obtained in ionizing a fragment of carcinoma tissue in the center of the pelvis by intermittent treatments, a few minutes or an hour per day out of 40 successive twenty-four-hour days? We are in acute need of knowing more about that What if ionization at depth, while physically quantitative, is in as yet unmeasured ways biologically qualitative—in other ways, I mean, than the matter of the exit dose? We need to know about that, just as badly

One minor but practical suggestion occurs to me about this most interesting paper I wonder if Mrs Quimby will, when this paper is published, or as soon as possible thereafter, give us the equivalents of these tables with several

other of the filters commonly used, such as 1 mm of copper, or the Thoracicus?

But sufficient unto the day is the illumination thereof I wish to express my great appreciation of the privilege of listening to, and of discussing, Mrs Quimby's most valuable paper

I have had the privilege of intermittent association with Mrs Quimby for a goodly number of years, and to my immeasurable advantage Through countless visits and telephone conversations she has resolved for me many perplexities, and eased many emergency tight-spots, always with kindness and patience, occasionally with a firm hand And one of the most firm-handed of her precepts was this "Remember, we have no right at present to try to express depth doses in roentgens" I have felt the weight of this dictum in various cross-firing problems, particularly in some studies I made correlating depth dose with lung changes in pulmonary radiation Now I rejoice that she has arrived at the point of permitting herself and us to measure depth doses in roentgens Most of us have done it, roughly and in contraband fashion I imagine, to express relative values to ourselves or make them more graphic to a clinician And I wonder, in passing, how many of us have exemplified cultural lag by doing this without stopping to think about back-scatter?

Suppose we are going to do a little mild ionizing of the pituitary (I refrain from calling it stimulation, or depression), in an amenorrhea case. We say "300 r through a lateral port, head 16 cm thick laterally, pituitary at 8 cm, value with such and such factors of 30 per cent at depth of 8 cm—about 90 r" Whereas from Mrs Quimby's chart it would be 114 r Not a great error, perhaps, in this low dose radiation, but a dangerous example of loose thinking How much sounder ground are we on now that we have a proved right to say, "I will ionize such and such tissue at such and such depths to the value of so many roentgens"

Dr. Carl B Braestrup, Physicist, New York City—Dr Quimby has very completely covered the important subject of dosage expression as well as the significance of the various physical factors applied in roentgen therapy

The described method of dosage specification deserves particular attention as it conforms closely to that of the Standardization Committee of the Radiological Society of North America Its recommendations were published in the form of standard dosage charts in the May, 1937, issue of Radiology The general adoption of these charts would assure a more uniform method of dosage expression, with ample accuracy for

clinical purposes. I believe Dr Quimby's clear exposition will do much to encourage the employment of all dosage factors.

However a distinction should be made between the factors controlling the incident radiation and the dose of the skin or underlying tissue. The quality and quantity of the primary beam have been determined with accuracy for the past eight or ten years. On the other hand, the measurement of the surface, and particularly of the depth dose, is still in the experimental stage. Varying results have been reported for identical conditions, depending upon the method of measurements. While the figures shown today may be the ultimate—although no such claim is made—there is still the possibility of further improvement in the determination of the tissue dose. Its evaluation, therefore, should serve mainly as a guide to the most effective treatment plan. For the duplication of technique, the factors of the incident radiation are, in my opinion more important.

For instance, even if the tables of the latest book on dosimetry are used the values of back scattering are different from the factors shown today. Dr Quimby's table, as well as our own measurements, indicated a definite decrease in back-scattering with increased ray quality in the range of deep therapy. Yet in this recent publication no such change is shown. We found a somewhat less decrease than Dr Quimby reported but that may be explained by the fact that our measurements were made with pulsating potential. I understand that Dr Quimby used constant potential and therefore possibly with a radiation of greater homogeneity for the same half value layer.

It is stated that if only a thin part of the body the hand for instance, does the scattering less radiation will be scattered back. This of course,

is true, but only if the hand is held free in air without any support of underlying scattering material. Such a procedure is not usually applied.

This brings up the question of the exit dose. We have found it possible to reduce this factor by about 8 per cent by removing the underlying scattering mattress. The following factors were used 200 kv peak 1 mm. cu filter H.V.L. = 1.3 mm cu 50 cm FSD 10 X 15 cm field and 21 cm. thickness. This would suggest that where the exit dose is high, such as with 400 kv and with long focal distances, the patient could be treated advantageously on a bed with a canvas top instead of a wooden table and mattress. Also that the head and neck could be treated with less exit dose when the patient is sitting up.

In Table II was shown the tissue dose in terms of the incident radiation rather than in percentage of the surface dose. This method has the advantage that the tissue roentgens can be derived directly from the r/min. in air. However as the skin dose usually is the limiting factor such figures do not indicate directly the relative advantages of different techniques.

Finally may I ask whether Dr Quimby 10 general by kv refers to the peak or to the constant potential equivalent value of the tube voltage? Also whether the indicated filters include the filtration of the tube and tube holder? In the self-contained apparatus neither factor can be determined directly and there seems to be some discrepancy between the manufacturer's value and those obtained by absorption measurements.

In conclusion, I wish to emphasize the importance of Dr Quimby's paper which so clearly demonstrates the application of accurate dosage expression.

COURSE IN TRAUMATIC SURGERY

A spring course in traumatic surgery has been arranged by Dr John J Moorhead of New York City for the Tioga County Medical Society. The lectures at Waverly N. Y., will be held at 6:30 P.M. at the Jenkins Inn. At Owego N. Y. the lectures will be held at the Green Lantern Inn at the same hour. On March 22 at Waverly Dr Henry H. Ritter will be heard on Burns

and Hand Infections on March 29 at Owego Dr H. M. Bergamini on Care of Head Injuries on April 5 at Waverly Dr Willis W. Lasher on Joint Injuries on April 12 at Owego Dr Emmett A. Dooley on Fractures of the Forearm and Leg and on April 19 at Waverly Dr David Goldblatt on Fractures of the Humerus and Femur

GALLBLADDER DISEASE

Optimum Time for Operation

HOWARD L. PRINCE, M D , Rochester, New York

As I look back to my internship, thirty years ago, the change in surgery of gallbladder disease is most striking. At that time, cholecystectomy was an unusual operation. This was because the mortality was high as compared with cholecystostomy. Drainage of the gallbladder was the general procedure, it was applied to three classes of cases: first, the normal gallbladder which was considered pathologic when the bile was dark and concentrated. Biopsies from these bladders were practically negative. In the second class was the slightly diseased gallbladder, with or without stones, "strawberry" gallbladder was a favorite diagnosis in this class. Biopsies from these gallbladders showed a variable amount of round cell infiltration and fibrosis. In the third class were the badly diseased gallbladders, usually with hepatitis, frequently with stones in the ducts, many adhesions, and often with jaundice. This last class of cases did badly. They had fever, were dehydrated and, inasmuch as the preoperative and postoperative treatment at that time usually led to an increase in dehydration, many died. Cholecystectomy was considered the height of rashness in these cases. The fact that practically all of the patients belonging to the second class—where the microscope showed definite pathologic changes—had recurrences in from one to four years was overlooked because patients were followed up in only occasional places. Once a patient had been operated upon and developed a recurrence of symptoms—whether in the upper abdomen or in the lower abdomen—he was assured by his lay and medical friends that the symptoms were due to adhesions. The first class—those we

now know to have been normal gallbladders—usually did well and added to the successful statistics of those times.

One of the first patients I saw, on returning to the small town to take my father's practice, was a woman of eighty-four on whose farm I had played as a boy. For twenty years, father had known that she had gallbladder disease and her history went back probably fifty years. Surgery had been considered inadvisable because of the risks attendant on her age. At this time, her attacks of severe pain, nausea, vomiting, and slight jaundice were following each other so closely as to be almost continuous. She insisted upon the operation, regardless of risk, and on the next Sunday morning—because Sunday was the day for operating in the country—on the kitchen table in the farmhouse, we removed the gallbladder under local anesthesia with the help of a few whiffs of chloroform at one stage. This woman recovered and was perfectly well until she died of pneumonia three years later. In consultation, a few months ago, I saw a woman with a long history of irregular indigestion with occasional attacks of severe pain, nausea, and vomiting. About six months before, she had been examined by a recent graduate of a very modern medical school with two years' hospital training behind him. He had recognized the condition and naively said to me, "I told her she might have to have something done some time." The time had not only arrived but the boat had pulled out from the dock. She was intensely jaundiced, with a high fever, and in addition to chronic cholecystitis with stones, she had a carcinoma of the gallbladder with metastases in the glands and in the liver.

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, May 11, 1938*

This shows that the state of the medical mind concerning gallbladder disease has not changed so much as would seem desirable. The well known nobility of the gallbladder to withstand repeated attacks or more or less acute inflammation has clouded our perspective. Thirty years ago, surgery had not advanced to the point of successfully handling the condition, at present it is capable of meeting the situation successfully except in a few instances. Colp and Ginsberg, in *Annals of Surgery*, January, 1937, remark that a consideration of the causes of death in gallbladder disease immediately discloses that, from the practical standpoint, they fall in three major groups. The first group is the one to which we should give a maximum amount of attention, for here the disease itself is the ultimate cause of the fatal issue. This too large group exists because the opinion that cholecystitis and cholelithiasis are relatively benign and harmless conditions, subjecting the patient to minor digestive disturbances and an occasional severe attack of colic, readily controlled by morphine, is still too widely held. The knowledge that cholelithiasis and biliary infection are actually treacherous foci of chronic infection and obstruction should be more widely diffused. The knowledge that a prolonged period of persistent low grade infection and of partial obstruction induces local changes which weigh the odds heavily against successful surgery should be more generally realized and applied. Through all the mass of literature there is this one point of agreement—that there is a certain mortality comprising a rather high percentage of the total mortality which is due to delay in resorting to surgery. This delay is due to the persistence of the teachings of many surgeons of years ago, driven to their opinions by their results at that time. Surgery was struggling for its place in the upper abdomen. Langenbush had done the first cholecystectomy in 1882 which was characterized by the great Lawson Tait as an operation "intrinsically absurd." Very much later, some eminent surgeons scoffed about the activities of their confreres

among the "cobwebs in the attic." All this background has had great influence in forcing patients with gallbladder disease into the upper age groups, by which time they have developed most of the complications of gallbladder disease as well as the handicapping features of years. Years ago stones were the most important thing to the surgeon and the contents of every gallbladder were carefully counted, the count was given the patient and Mrs. Jones with four hundred gallstones was a much more important person than Mrs. Smith with two hundred gallstones.

Kehr, the Mayos, Moynihan, and many others began preaching the importance of infection in the gallbladder wall which demanded removal of the gallbladder rather than drainage. As the importance of the patient's general condition became appreciated and his disturbed physiology considered, cholecystectomy began to come into its own as the procedure of choice in the handling of gallbladder disease. Nevertheless, it has taken years more to bring the question as to the best time for operation to the fore. Earlier, the high mortality of surgery had made delay advisable. If the patient died unoperated, it was an act of God. Only the toughest and best able to survive ever arrived at the operating table. In the last fifteen years, more and more men have been thinking and writing about the desirability of early operation during the acute attacks of gallbladder disease. A study of the literature is fascinating and thought provoking—fascinating in the complexity of the findings. Anyone can find numerous statistics, researches, animal experiments, opinions, etc., to support whatever ideas he may have. To articles arriving at diametrically opposed conclusions will be attached long bibliographies surprisingly alike. It is thought provoking in that it makes one wonder how supposedly equally intelligent men can arrive at such opposite notions based on the same procedures in the experimental laboratory. My own fancy is that the true research mind is very much rarer than the ambitious research doing body. The result of this great urge

are the "duration of symptoms referable to the gallbladder before the onset of the acute attack and the age of the patient at the time of operation"

I wish that some influential organization would wage an active campaign to bring these well established facts to the attention of the medical profession. Many lives could thus be saved.

Dr Thew Wright, *Buffalo*—Dr Prince's views and mine on the subject of gallbladder disease and its management are so similar that in discussion of his paper I can do little more than lay additional emphasis upon some of the points he has called to our attention.

The unfortunate results of delay in bringing the patient to surgery should, I think, be stressed. To operate upon early and mild cases of gallbladder dysfunction is no more called for than in the case of peptic ulcer. Sane and carefully managed medical care has cured many a patient of both of these conditions. Such treatment is justified and I believe should be tried in all cases of mild or so-called chronic cholecystitis without stones and with only an occasional attack of colic. I believe that medical treatment as outlined by Mock, Brown, and Dolkart to which the doctor has referred will give far better results than the older, more accepted methods. But to persist in any form of medical treatment that does not give complete relief, and that continuously, is, I believe, unwise. Cases with proved stones I feel are surgical, and medical treatment is merely a makeshift that subjects the patient to the probability of serious trouble and offers no assurance of prolonged health.

The dangerous effect of chronic biliary infection and intermittent obstruction should, as Dr Prince has said, be more generally appreciated. I agree with him that there are some differences between a diseased gallbladder and a diseased appendix, but I have stated many times that as no one has ever died from simple appendicitis,

no one has ever died from simple cholecystitis. It is the complications due to procrastination and delay in bringing the patient to surgery that cause the mischief in both diseases. Cases of cholelithiasis and cholecystitis are allowed to go from year to year without surgery until complications arise that demand surgery in a patient whose resistance has been lowered and who presents a condition which demands the highest surgical skill and is often beyond human power successfully to combat. I agree wholeheartedly with the doctor that cases of acute cholecystitis should be promptly operated upon. For more than twenty-five years I have practiced and taught early operation in this condition. During a large part of this time it has seemed to me that eminent surgeons whose vision was clear on most subjects have been befogged in this through an ungrounded fear of the danger in operating on cases of acute cholecystitis and have advised an attitude of watchful waiting, permitting the more serious complications of gangrene and perforation of the gallbladder, suppurative cholangitis, pyelophlebitis, and damage to the liver itself to be superimposed upon a condition that early operation would have cured promptly. It is a source of gratification to me to see the steadily increasing number of leaders of surgical thought whose views coincide with those that I have held for many years. Time should, of course, be taken to overcome dehydration and to properly prepare the patient for operation, which procedure rarely necessitates more than a few hours' delay. Fortunately, in the vast majority of cases, progress to perforation or gangrene is slower in the gallbladder than in the appendix so that the necessity of immediate operation may not be quite so urgent.

As Dr Prince says, "No man can foretell the course of any given attack of gallbladder disease." When we educate the internist and the laity to look upon acute cholecystitis as we do upon appendicitis we will greatly lessen the mortality of this disease.

SULFANILAMIDE MAY DAMAGE LIVER

Sulfanilamide may cause severe damage to the liver, Curtis F. Garvin, M.D., Cleveland, says in the *J.A.M.A.* for December 17. He cites five cases of inflammation of the liver that occurred from the therapeutic use of sulfanilamide.

Three of these cases showed an associated scalp skin infection. One case ended fatally. The other patient, with a simultaneous occurrence of jaundice and abnormal accumulation of fluid in the abdominal cavity, recovered.

PIGMENT CIRRHOSIS

Rate of Occurrence and Difficulties in Diagnosis

JAMES R. LISA, M.D., and JAMES FINLAY HART, M.D., New York City

From the First Medical Division, Service of Dr. John Carroll and Pathologic Laboratory, New York City Hospital, Welfare Island Department of Hospitals

THIS communication is the report of a study of the cases diagnosed as pigment cirrhosis at the New York City Hospital from January 1, 1920, to December 31, 1937. During that time there were 7 such cases recorded and there were 124,600 admissions to the hospital.

We use the term pigment cirrhosis in preference to either hemochromatosis or bronze diabetes because we feel that it is the most inclusive of the three designations. The deposit of pigment in the parenchymatous and other cells of the liver is generally accepted as the primary essential lesion and this, with the accompanying cirrhosis, is the one finding common to all.

Pigment cirrhosis is generally considered to be a rare disease. Sheldon,¹ after a very exhaustive search of the literature, concluded that 311 positive cases had been reported by 1935. He refused to accept 34 because they lacked reliable evidence for the diagnosis. He considered it a rarity but thought it was probably more common than is usually believed. Althausen and Kerr² quote 3 cases in 60,000 admissions to the University of California Hospital (0.005 per cent), and there were 3 in 106,000 admissions to The Johns Hopkins Hospital (0.003 per cent).³ These are close to the percentage we found (0.0056 per cent). Bntt and Wilder⁴ stated that they had been able to recognize 30 cases during life at the Mayo Clinic in fifteen and one-half years and confirmed their diagnosis by skin biopsies.

Sheldon advised the use of postmortem figures in estimating the frequency of the disease. He quotes Stewart's figures which give 52 cases in 38,096 autopsies in the British hospitals with 13 cases in six

teen years in his own hospital in Leeds. At Boston, Rowen and Mallory⁵ found 3 cases in 6,508 autopsies (0.05 per cent), Blanton and Healy⁶ found 4 cases in 5,000 postmortems in twenty eight years at Bellevue Hospital (0.08 per cent), Mills⁷ met with 16 cases in 3,700 autopsies during twenty six years (0.4 per cent), and Krall and Ginsburgh⁸ found 3 cases in 1,435 autopsies (0.2 per cent). There were 3,621 postmortems at the New York City Hospital during the eighteen years considered in this paper. Only 4 of the 7 reported cases came to autopsy however, which gives us a percentage of 0.11.

The diagnosis of pigment cirrhosis is difficult to make. In the final analysis no case can be considered positive without a biopsy of the liver. Even here, error may enter. There must be a cirrhosis and there must be a pigment within the connective tissue. A differential diagnosis from biliary cirrhosis is essential. In this case there may be marked pigmentation in the parenchymal cells and the bile duct epithelium but there is little or none to be found in the connective tissue. Mallory⁹ thinks that in the early stages even the pathologist may occasionally miss it.

A clinical diagnosis may be erroneous either by commission or by omission. The presence of diabetes and cirrhosis in the same patient is not commonly seen, but when it does occur it usually draws the attention of the clinician to pigment cirrhosis. Calling such a combination pigment cirrhosis without further proof is probably the commonest error of commission. Mistaking other forms of skin discoloration for the pigmentation of this condition explains the remaining errors in this group. The skin changes seen in Addison's disease, argyria, and some of

the darker forms of jaundice may closely simulate those of pigment cirrhosis. Then, as the disease may be present in the absence of any or all of the recognized triad of clinical signs, it is not difficult to see that errors of omission are frequent in the diagnosis.

A diagnosis of pigment cirrhosis based upon the clinical interpretation of a pigmented skin is of very little value. If the case is seen in the late stages there may be a bronze to a dirty gray pigmentation with a metallic sheen most prominent over the external genitalia, the exposed parts of the body, or in scars. When seen in the early stages, however, these characteristics are rarely evident. Here the skin usually cannot be differentiated from the pigmented skin commonly seen in the aged and those with chronic diseases.

A positive diagnosis from sections of excised skin or glands can be made under certain conditions. The presence of pigment granules localized around the sweat glands in the corium is generally accepted as typical of pigment cirrhosis. Less frequently, hemosiderin granules may be found in large quantities in the connective tissue cells and still less frequently, they may be seen in the endothelium of the capillaries and small vessels. In the lymph nodes the pigment is not so constant, its presence depending on the area they drain. When present there is nearly always a naked eye pigmentation, being a deep brown color which becomes bright yellow on section. In the mildly involved specimens the reticulo-endothelial cells of the sinusoids are most pigmented. Later the cortex becomes more pigmented than the medulla, and in the severe cases the gland is so thoroughly saturated that the anatomy is obscured.

A certain percentage of cases, however, may not show pigmentation. In 235 cases collected by Sheldon, 38, or 16.2 per cent, gave a negative history. Again, in 214 cases pigmentation of the skin was the first complaint in 55, or 25.7 per cent. He feels that 16 per cent of the cases will fail to show the positive skin test throughout their course and this may go as high as 75 per cent in early cases. Yet he be-

lieves that with better reporting it will be found that pigmentation of the skin will have the greatest chance of being the primary symptom.

Case Reports

In 2 of our cases the diagnosis was proposed during life. In each one it was based entirely on a clinical estimate, as no positive skin biopsy or autopsy was obtained. Two left the hospital after a short stay and 1 died of pneumonia. In 1 case there was cirrhosis, diabetes, and pigmentation together. We could hardly call any of these undoubted cases of pigment cirrhosis, and therefore they are not used in the final statistics.

The three case histories follow.

J. J., male, 49 years old, was admitted April 26, 1923, as carcinoma of the liver and diabetes mellitus. His chief complaints were pain and swelling in the abdomen. Six months before admission he was in good health. Swelling of the abdomen began first, and at that time he was told by a physician that he had diabetes. The liver became tender and he noticed that the exposed part of his skin was getting darker. He claimed a good appetite with no vomiting or gas, yet he lost 27 pounds in a year. On examination he showed a "dusky red" tint to the skin and the pigment of the skin of the legs was "like that of the face." The abdomen showed marked ascites and the liver was stated to be two fingers below the margin of the ribs. The spleen was not felt. There was edema of the ankles. On the 7th of May, there was 4 per cent sugar in the urine. On the 11th the sugar was 1 per cent and on the 14th it was negative. On the 24th it was noted that the color of the skin was getting deeper and on the 27th it was a deep bronze color. He signed out of the hospital on the 27th of May. He denied venereal disease and his Wassermann was negative. All other laboratory tests were negative. A biopsy of the skin showed moderate hyperkeratinization with moderate atrophy of the epidermis and thickening of the dermis. There was no evidence of pigment.

Wm. J. M., male, 53 years old, was admitted August 4, 1933, as a case of chronic lead poisoning. His ward diagnosis was cirrhosis of the liver, chronic cardiovascular disease, and cerebrospinal lues. His chief complaints were distention of the abdomen and retention of the urine. He was a painter by trade and had a history of lead colic. He was told twelve years previously that his liver was below the costal margin. He

had been tapped three weeks earlier and two gallons of fluid were removed. He always had a dark complexion but it seemed to him to have increased in the last seven years. It came first on the hands and feet and then on the whole body. On examination he showed a generalized pigmentation of the skin. The liver was palpable four fingers below the ribs was hard and nodular but not tender. There was evidence of fluid in the abdomen and the legs showed edema. The urine contained two plus sugar and the blood sugar was 100 mg before breakfast. All other laboratory tests were negative.

On August 8th the attending physician said: General pigmentation of an olive-brown type as distinguished from negro color. Face almost greenish gray and much darker than any other part of the body. No color to conjunctiva although the eyeballs are somewhat blue. Lips pigmented looking cyanotic. Hard palate and throat the same tint. No excess of color on knees or elbow. A skin biopsy was ordered. The patient asked for a release on August 13 1938.

T B, male 55 years old was admitted October 27 1936 as a diabetic with cirrhosis of the liver. He had known of his diabetes for three years. His abdomen first distended five months previously and he had been tapped six times before he entered. He claimed to have lost twenty to thirty pounds in the last two years. He denied venereal disease and excessive drinking. On physical examination there was fluid in the abdomen and the liver edge was felt four fingers below the ribs. It was reported as smooth. There was no statement of pigmentation in the clinical history. The Wassermann was negative. He was on a diabetic tray and 45 units of insulin a day. He died of pneumonia on January 10 1937. There was no autopsy performed.

The remaining 4 cases of the series were not recognized clinically as pigment cirrhosis. They were the 4 that came to autopsy and the diagnosis was made unexpectedly in each case upon the histologic examination of the liver. The histories of these cases follow.

Autopsy 1950. A K, a white male, 54 years old, was admitted to the hospital November 29 1922 as a paraplegic. He had been a dish washer of late but had worked as a farmer, painter and carpenter. He had measles twice and mumps once in childhood. He had three attacks of erysipelas at 22, 29 and 51 years respectively. At 34 he had an attack of bronchopneumonia from which he recovered in three weeks. At 45 he had a bilateral herniorrhaphy. He lost about 25 pounds in the last two years.

He denied venereal disease but admitted being a heavy beer drinker.

On November 3rd he suffered a stroke of apoplexy which left him with a total right-sided paralysis and a marked speech defect. His course was uneventful until February 7 1923 when he had an epileptiform seizure. On July 5th he became comatose and death occurred that evening. The autopsy showed a slightly enlarged liver with cirrhosis. The histologic examination disclosed a Laennec's cirrhosis with a very dense deposit of golden brown pigment in the connective tissue. There was also a primary carcinoma of the liver recognized.

Autopsy 2888. D C, male, 47 years old entered the hospital April 3 1928 as a cardiac in decompensation. The heart sounds were weak and distant but no murmurs were found. The liver was down three to four fingers below the costal margin extended across the abdomen and was hard. There were no ascites or edema. On April 6 1928, the day he died, he was noted to have a slight icterus. All his laboratory reports were negative.

At autopsy the liver weighed 1700 grams, the capsule was smooth and shiny and the tissue beneath presented a smooth yellow brown appearance. It was firm in consistency and was normal in shape and size. On section it presented a moderate sclerosis and a chronic passive congestion. The heart showed an acute rheumatic myocarditis and pericarditis.

The histologic examination of the liver showed a marked increase in the periportal connective tissue and these areas were heavily infiltrated with hemosiderin bearing phagocytes. The areas also had a marked lymphocytic infiltration. The nodules showed extreme fatty changes. The spleen contained a large number of hemosiderin bearing cells most marked in the pulp and in the trabecular and central areas. There was a marked fibrosis and a moderate diminution in cellular elements. The capsule was markedly thickened.

There was no evidence in any other organ. At the time of the autopsy the skin was noted as being white. The anatomic cause of death was acute rheumatic carditis.

Autopsy 4685. L K, a male 50 years old was admitted March 19 1936 and died March 20 1936. On admission he was considered to be a possible secondary carcinoma of the liver. His chief complaints were lumbar and sacral pain with weakness and loss of weight for a year. On examination he was found to be slightly jaundiced. The liver was below the umbilicus, regular and firm. There was no ascites. The spleen was very large. There is no record of

sugar in the urine but a fasting blood sugar was 121 mg. The Wassermann was negative. There was no statement of pigmentation of the skin. On autopsy a Laennec's cirrhosis was found. There was an enlarged spleen. Histologically the liver showed pigment cirrhosis. His icteric index was 15.

Autopsy 4892. C. K., a white male, 71, was admitted April 19, 1937, and died April 21, 1937. His chief complaints were difficulty in swallowing and breathing with marked loss of strength. The entrance diagnosis was possible carcinoma of the esophagus. He admitted being a heavy drinker and said the illness began one year ago. The only relevant finding was a mass in the abdomen. There was no clinical history of cirrhosis or diabetes or pigmentation. The autopsy showed a "white" skin, a small cirrhotic liver, and a small spleen. The histologic diagnosis was pigment cirrhosis.

Discussion

From our findings in this series it would seem that pigment cirrhosis is a rare disease. Estimating its occurrence from the clinical standpoint we note that in 124,600 admissions to the hospital there were only 2 cases in which it was suspected during the patient's stay. Relevant to this is the fact that the New York City Hospital has a large chronic population with a full quota of diabetics and cirrhotics. Furthermore, these cases give ample opportunity for observation as they stay in the hospital comparatively long periods of time. On the other hand, if we estimate from the postmortem figures, we find our percentage about the average given in the literature. With 4 positive cases in 3,621 postmortems, we run 0.11 per cent which comes close to the idea of Polson¹⁰ that 1 case is found in each 1,000 autopsies. From our study we have become impressed with the advisability of using postmortem statistics as the basis for establishing the occurrence.

The clinical diagnosis in our cases

proved very difficult to make. One diagnosis, made before the patient was removed from the medical service, became unacceptable after a negative skin biopsy. It showed that a noticeable pigmentation of the skin associated with diabetes and cirrhosis does not necessarily mean pigment cirrhosis. Another gave no evidence in the history that it was considered pigment cirrhosis. From all appearances, the diagnosis was written at the discharge and here the resident physician, apparently influenced by the presence of diabetes and cirrhosis in the same case, recorded pigment cirrhosis in the history.

Skin biopsies are noticeable by their absence. Evidently cases of pigmented skin suggesting a skin biopsy were very rare in the hospital during the sixteen years.

The diagnoses in the cases that came to autopsy were made on the histologic examination of the liver. With the exception of a spleen showing pigmentation, there was no evidence from the reports that any other organs were involved.

Conclusions

1. Pigment cirrhosis is of rare occurrence.
2. A clinical diagnosis is difficult. Errors are due to both commission and omission.
3. The final diagnosis rests on the histologic changes of the liver.
4. A biopsy of the skin is of value only when positive findings are obtained.

CLINICAL COMPARATIVE STUDY OF ANESTHETICS IN 1,370 CASES OF THORACIC SURGERY

Cyclopropane, Evipal, Avertin, Gas-Oxygen, Regional and Local

POL. N. CORYLLOS, M.D., F.A.C.S.,[†] and SARA BASS, M.D.

(Director of Surgery and Chief Anesthetist, Sea View Hospital Staten Island New York)

IN THORACIC surgery anesthesia is a factor of greater importance in the outcome of the operation than in any other branch of surgery. Patients with chronic suppuration of the lung, such as pulmonary tuberculosis, bronchiectasis, abscesses, are cases of chronic anoxemia who cannot stand any further decrease of oxygen unsaturation. The latter may occur either during the operation or during the postoperative period. The most frequent cause of increased anoxemia is retention of exudate with or without bronchial obstruction, atelectatic and inflammatory consolidation of the lung or spread of the infection in the healthy lobes of the lung.

In cases without chronic suppuration, such as tumors of the lung or the mediastinum, or operation upon the esophagus the problems are different. Keeping respiration quiet—so as to allow sufficient collapse of the lung and room for the operation—inducing apnea when necessary, and at the same time insuring satisfactory oxygenation for a long period of time, are the main problems of anesthesia. It is obvious that although the anesthetic used is of less importance than the skill and experience of the anesthetist, we should not neglect the advantages offered by each of the special agents at our disposal. Therefore, perfect knowledge of their respective physiologic action, their special advantages and shortcomings is necessary in order to choose the right anesthetic for each individual case.

Our aim in this study is to report our experience with different anesthetics on 1,370 chest cases, most of which were

patients with pulmonary tuberculosis. For purposes of comparison, we have added 100 nonthoracic cases operated upon under cyclopropane anesthesia. These anesthetics were administered at Sea View Hospital from December, 1932, to March, 1938. Of the 1,370 chest cases, 300 had cyclopropane, 212, gas oxygen, 226, avertin 605, evipal and 27, regional and local.

Cyclopropane

We became interested in cyclopropane as an anesthetic agent because of the high oxygen concentrations possible with this gas. During operation for thoracoplasty, the anoxemic condition is aggravated as the patient lies on his sound side, thus limiting respiratory excursions. By relieving this condition of anoxemia during operation with an anesthetic gas that offers a high concentration of oxygen we hoped to reduce the morbidity and mortality resulting from postoperative pulmonary complications.

Cyclopropane, C_3H_6 , an isomer of propylene, was investigated by von Freund¹ in 1882, but not until 1929 was its anesthetic possibility considered. At that time Henderson and Lucas² published their results on animal experimentation with the gas which was then in a somewhat impure form. Waters³ of the University of Wisconsin received the gas in purified form and continued the experimentation on animals and was the first to use it clinically. We are indebted to him for his excellent work which paved the way for a widespread clinical application of this valuable addition to the armamentarium of the anesthetist.

[†] Died July 26 1938

TABLE 1—AVERAGE DURATION OF OPERATIONS PERFORMED UNDER CYCLOPROPANE ANESTHESIA

| TYPE OF OPERATION | No | AVERAGE OPER TIME |
|----------------------------------|-----|----------------------|
| Thoracic— | | |
| 1st stage thoracoplasty | 148 | 1 hr 10 min |
| 2nd stage thoracoplasty | 45 | 50 min |
| 3rd stage thoracoplasty | 12 | 51 min |
| 3rd stage and revision thor | 8 | 1 hr 16 min |
| 3rd stage and Schede | 6 | 1 hr 12 min |
| Revision of thoracoplasty | 33 | 1 hr 30 min |
| Schede | 27 | 1 hr 11 min |
| Sinus revision | 15 | 1 hr 17 min |
| Lobectomy | 4 | 1 hr 32 min |
| Pneumonectomy | 1 | 2 hr 23 min |
| Subtotal scapulectomy | 1 | 49 min |
| Orthopedic— | | |
| Spine fusion | 34 | 1 hr 15 min |
| Joint fusion | 12 | 50 min |
| Miscellaneous | 34 | 30 min |
| Nephrectomy | 6 | 1 hr 20 min |
| Suprapubic cystotomy | 1 | 50 min |
| Excision of glands | 5 | 20 min |
| Appendectomy | 2 | 43 min |
| Laparotomy | 2 | 55 min |
| Incision and drainage chest wall | 1 | 11 min |
| Biopsy cervix | 1 | 15 min |
| Dilatation and curettage | 1 | 11 min |
| Vaginal hysterotomy | 1 | 45 min |

Several reports^{4,5,6} have appeared in the literature concerning cyclopropane anesthesia in thoracic surgery. Eversole and Overholt⁴ consider cyclopropane the most satisfactory anesthetic agent for operations on the chest. Rovenstine,⁶ in a review of 160 thoracic operations with cyclopropane anesthesia, concludes with the statement that somewhat better surgical results may be obtained with this anesthesia than with other agents in common use.

In this report, we present the results obtained with 400 cases of cyclopropane anesthesia, 300 of which were given for thoracic surgery and 100 for mainly orthopedic surgery. We used the cyclopropane manufactured by E R Squibb & Sons for all of our cases.

In Table 1 we have enumerated the various types of operations for which we used this gas, and the average operative time for each. Our patients ranged in age from 2 to 65 years.

The patients undergoing thoracic surgery received $\frac{1}{6}$ to $\frac{1}{3}$ grain of pantopon and those for the nonthoracic operations, morphine sulfate, gr $\frac{1}{12}$ to $\frac{1}{4}$, and atropine sulfate, gr $\frac{1}{300}$ to $\frac{1}{150}$, one to one and one-half hour, preoperatively.

In all patients who expectorated more than one ounce of sputum in twenty-four

hours we used the endotracheal catheter so that we could aspirate any excessive secretions from the respiratory airways before, during, and after the operation, our procedure has been described in detail elsewhere.⁷ For the same reason we used the catheter in cases with empyema and open bronchopleural fistula and in the cases of pneumonostomy, lobectomy, and pneumonectomy. In this way the anesthetist has direct control of the anesthesia and of the degree of the inflation of the lungs at all times.

In administering cyclopropane we used the closed carbon dioxide absorption technic. We prefer the slow induction with the soda-lime filter included in the circuit from the very beginning of anesthesia. The bag is filled with oxygen and the mask is then applied to the patient's face. The patient takes several breaths of oxygen while the mask is adjusted and tested for leaks. An airtight connection is desirable for a smooth course of anesthesia. Cyclopropane is introduced at the rate of 300 to 400 cc per minute and the oxygen flow is decreased to about 400 cc per minute. After three to five minutes, the lid reflex is lost and the cyclopropane flow is entirely shut off and anesthesia is maintained with a constant flow of oxygen approximating as closely as possible the metabolic needs of the patient. If anesthesia becomes too light, cyclopropane is added at intervals as needed. In two-thirds of our cases, we used the interrupted method as described above and in one-third the continuous flow method of administration as described by Burford.⁸

For the thoracic and orthopedic operations, anesthesia in most instances was carried on in the first plane and upper level of the second plane of anesthesia as no marked degree of muscular relaxation is required. It was necessary to supplement a small amount of ether, from a few drops to one ounce, in six of the 300 thoracic operations, whereas in the nonthoracic cases, 12 patients required ether, from a few drops to two ounces.

Induction is usually quite rapid and remarkably smooth. Such an induction

is a distinct advantage in thoracic surgery as it precludes the possibility of further damage to the involved lung parenchyma as well as the danger of spread of disease to the healthy portions of the lungs. However, some degree of excitement was encountered in 12 per cent of our cases. In only 1 case was it violent.

Cyclopropane is not a respiratory stimulant. During induction there is no increase in rate and minute volume respiration, as found with other inhalation agents. The quiet respiration which prevails throughout the anesthesia is of great aid to the surgeon operating on the open chest and lung.

Apnea occurred in 59 (19.7 per cent) of the thoracic cases. In 9 of these the period of apnea took place during induction, and in 27 it occurred when the periosteum of the rib was being removed by the periosteal elevator. We have long observed that respirations are irregular and labored during scraping of the periosteum no matter what anesthesia is used. This phenomenon occurs just as frequently under local anesthesia as under general anesthesia. The period of apnea that takes place at the time of removal of the periosteum is usually of short duration, lasting from a few seconds to a minute. Respirations recur spontaneously. However, if breathing is not resumed spontaneously in a few seconds, we maintain artificial respiration by rhythmic pressure of the breathing bag in order to prevent any extreme fatigue of the respiratory center.

It was necessary to resort to mouth to mouth insufflations in 6 of the instances of apnea in order to restore respiration. In 1 case, anesthesia was proceeding uneventfully when suddenly the patient stopped breathing. There was no change in pulse. This dramatic cessation of respiration supervened as a direct result of manipulation of the mediastinum during decollation of the lung in a first stage thoracoplasty. Immediate mouth to mouth insufflations were instituted and in about one minute the patient began to breathe and anesthesia was continued

with no other untoward complications. This is but one example of the importance of constant attention on the part of the anesthetist during anesthesia for thoracic surgery.

During anesthesia with cyclopropane for the nonthoracic operations, short periods of apnea were encountered in 7 per cent of the cases. In only 1 patient, an obese negro woman of 48, was it in any degree alarming. Apnea occurred a few minutes after anesthesia was begun. Rhythmic pressure on the breathing bag and artificial respiration by rhythmic pressure on the chest did not restore respiration. The mask was removed, rhythmic pressure on the chest was continued, and in one minute full consciousness returned. The operation which was for excision of a chest wall sinus, was carried out under local anesthesia.

Of interest is the marked rise in blood pressure that occurs during cyclopropane anesthesia. There was an average rise in systolic blood pressure of 27 mm. of mercury in our series of cases. In 42 per cent the systolic rise was 30 points or more with no change in pulse pressure. Two or three minutes after induction, the systolic pressure rises 20, 30, or more points, and is maintained at that level for approximately one-half hour and then if operative shock sets in, from bleeding or any other cause, the pressure starts to fall, sometimes quite rapidly. Replacement of fluids lost from the tissues usually prevents the rapid fall in blood pressure. It has been our custom in long, severe operations and in poor risk cases to start an infusion of 5 per cent dextrose immediately preoperatively and to continue it throughout the operation. If much bleeding takes place, a transfusion of citrated blood can be given at any time during the operation. This procedure has markedly lessened the shock in many of our poor risk patients.

In a few cases the blood pressure rose toward the end of the operation rather than during induction. In these instances, there was usually a marked drop

in blood pressure as soon as the mask was removed

Rowbotham,⁹ in a series of 250 cases, found a rise in systolic pressure of 10 to 30 mm of mercury shortly after induction. He states that the higher the concentration of cyclopropane, the higher the elevation of the blood pressure, even when the anesthesia reaches almost to the stage of respiratory arrest. Bogan¹⁰ reports a definite rise of 10 to 20 points above the preoperative systolic pressure, usually without change in pulse pressure, throughout the anesthesia in one-half of his series of 315 anesthetics with cyclopropane. In his experience the rise in blood pressure was accompanied by a slowing of pulse. We noticed this concomitant slowing of pulse in some, but not in all of our cases. Contrary to Rowbotham's findings, we had no lowering of systolic pressure when we decreased the concentration of cyclopropane.

Waters¹¹ reports an occasional rise in blood pressure after induction. He can find no clinical or experimental evidence to support the belief that cyclopropane raises blood pressure. He points out that the common causes of an elevated systolic pressure in anesthesia are carbon dioxide excess, oxygen want, or respiratory obstruction. He adds that careful consideration should be given to possible technical errors and particularly to the likelihood of inefficient carbon dioxide control.

We are of the belief that more bleeding and capillary ooze take place under cyclopropane anesthesia. This is in disagreement with the statements of Waters³ and others, who believe that the bright red color of the blood simulates an actual increase in the amount of blood. Rowbotham,⁹ however, finds a definite increase in capillary bleeding with cyclopropane anesthesia. Griffith,¹² likewise, is convinced that there is a greater tendency to capillary oozing and he believes it is due to a vasomotor effect on the smaller arteries and not to any chemical change in the blood affecting coagulability or viscosity.

Schmidt and Waters,¹³ in reviewing 2,200 cases of cyclopropane anesthesia at the Wisconsin General Hospital, found a larger proportion of circulatory disturbances with this gas than with others. In a later report¹⁴ from the same institution, embracing 5,889 cases of cyclopropane anesthesia, the same conclusion is arrived at. Likewise, they found that arrhythmia was diagnosed more than twice as often with cyclopropane than with ether, and that arrhythmias occur more frequently with deep than with light cyclopropane anesthesia. EKG studies by Kurtz *et al*,¹⁵ made on 44 cases during anesthesia with cyclopropane, show cardiac involvement in all but 18 per cent of the cases. We did no EKG studies in our series during anesthesia but, by palpation of the temporal artery, noticed cardiac irregularity in 10 per cent of the cases. It is our habit to keep the finger on the temporal pulse throughout the anesthesia, thus we feel that we did not overlook any irregularity of the peripheral pulse. The arrhythmias we noticed lasted from a few seconds to about ten minutes. In only 1 patient did we note any postoperative arrhythmia. Throughout the anesthesia his pulse remained regular, but four hours following the cessation of anesthesia he developed skipped beats with a 3 to 4 rhythm. The irregularity lasted two hours, during which time an EKG revealed premature auriculoventricular extrasystoles. EKG's taken on this patient several days preoperatively and six days postoperatively were interpreted as normal.

Several observers consider arrhythmia as a danger signal of overdosage of cyclopropane. In our experience, we could not consider it as such because the arrhythmia in every instance occurred during the stage of induction or light anesthesia.

During the early period of anesthesia, slowing of the pulse is a fairly constant finding with cyclopropane anesthesia, as anesthesia progresses, the pulse rate always rises. Waters³ considers a rate below 50 one of the danger signals of

overdosage of the anesthetic agent. We had no instance of marked slowing of the pulse rate. Conversely we are in agreement with Waters that a definite increase in rate is a danger sign. In our series of cases, the pulse rose from a preoperative average of 108 to an average high of 133. At the end of the operation, the average pulse rate was 128.

Cyclopropane is not an irritant. There fore an extremely high concentration can be inhaled without producing laryngospasm. We had no instance of laryngospasm in our series.

We noticed that cyclopropane does not depress the cough reflex. This is of distinct advantage in thoracic surgery as the bronchial secretions can be expelled, thus reducing the danger of postoperative bronchial obstruction. We made a note of every instance of cough, even when it occurred only once, and found that 22 per cent of the patients coughed during the operation. In none was cough troublesome enough to interfere either with the operation or the anesthesia. As would be expected, cough occurred less frequently (8 per cent) in the non-thoracic operations. In the former, manipulation of the pleura and lung, especially of the diseased apex, often produced cough.

In many cases there was a marked drop in blood pressure with coincident shock as soon as the mask was removed at the end of the operation. This sudden drop in blood pressure averaged 17 mm. of mercury. It was suggested by Dr. Neff¹⁷ that this might be due to a sudden withdrawal of a humid and warm atmosphere, rich in oxygen, and that if we diluted the anesthetic mixture with air or nitrous oxide toward the end of the operation, we might avoid this alarming symptom. We adopted his suggestion, and in a series of 27 cases we diluted the anesthetic mixture with nitrous oxide during the last 20 to 30 minutes of anesthesia. The systolic pressure in these cases fell from 106 mm. of mercury to 95 mm. of mercury, a drop of 11 points. Air was used in the same diluting manner in 194 cases and the systolic pressure

| Shock—total | 100 | 33.3 | 4 | 14.8 |

evipal series¹⁸ (39 per cent) However, only 2 per cent of the total number of patients vomited more than one day

Upon casual observation, it may appear that operative shock occurred in rather a large percentage (35.3) of patients following thoracic surgery This may be readily understood when we consider that all our cases have far-advanced pulmonary tuberculosis and many are complicated by contralateral involvement, contralateral pneumothorax, and empyemata of tuberculous or mixed origin They are in poor physical condition, having spent long periods of time in bed, secondary anemia is a common finding, and not infrequently is amyloidosis a complicating factor In addition, they have undergone a long and severe operation

The most alarming and sometimes fatal complication we have experienced is the sudden onset of convulsions Generalized convulsions occurred in 5 of the 300 anesthetics given for thoracic surgery, none took place in the non-thoracic series Twitchings of the eyelids and facial muscles were seen in 2 other cases and carpopedal spasms in 1 other We deem it of interest to present a short résumé of these cases

Case 1 B S, age 42, white male Seventeen minutes following induction, marked generalized convulsions set in with cyanosis, weak and slow pulse, 40 per minute, and the blood pressure could not be recorded E & J resuscitator was applied Respiration was maintained but there were repeated convulsions until death ensued 50 minutes following induction Vessels of the head and neck were engorged Postmortem examination revealed cerebral edema, pulmonary caseous-pneumonic tuberculosis, dilatation of the right auricle and ventricle with myocardial fibrosis

Case 2 A C, age 25, white female One hour and seven minutes following induction for a first stage thoracoplasty, there was a sudden occurrence of generalized convulsions The mask was removed and oxygen was given through the endotracheal catheter There was a series of four convulsions lasting 30 seconds each with intervals of 15 seconds Three ampules of coramine were injected intramuscularly Respiration became very shallow, slow and laborious,

so mouth-to-mouth insufflations were instituted and an infusion of 5 per cent saline begun Convulsions continued at frequent intervals until patient died 45 minutes following the first convulsion Veins of the neck were markedly distended and clinical diagnosis was pulmonary embolism At postmortem, caseous pneumonic tuberculosis, tuberculous empyema, dilatation of all the heart chambers, patent foramen ovale, and tuberculous myocarditis were found Brain was not examined

Case 3 A McD, age 47, white female Second stage thoracoplasty was performed Anesthesia was uneventful and patient was conscious six minutes following removal of the mask Eight hours postoperatively patient went into coma and developed stiffness of the neck, twitching of eyelids and spasticity of the arms Legs were flaccid and all deep reflexes but the plantar were absent Three and a half hours later she had a generalized convulsion. She died one and a half hours later No autopsy was performed Clinical impression favored cerebral embolism as the cause

Case 4 S T, age 33, negro female Operation was for revision of thoracoplasty and packing of cavity with muscle flap Infusion of 5 per cent saline and transfusion were administered throughout the operation Anesthesia was uneventful until one hour and forty-two minutes following induction, when two convulsive seizures occurred each lasting a few seconds The mask was immediately removed, two cc of bloody mucus were aspirated through the endotracheal catheter, and carbon dioxide-oxygen was given by mask The operation was quickly completed No further convulsions occurred and she was conscious forty minutes postoperatively (one hour following the convulsions) Recovery was uneventful

Case 5 M V, age 12, negro female Second stage thoracoplasty Anesthesia was uneventful until forty-eight minutes following induction when a generalized convulsion took place The mask was removed and oxygen was administered Convulsion lasted one minute. Two minutes before the onset of the convulsion, 3 cc of metrazol had been injected intravenously for falling blood pressure Operation was completed and the patient was conscious 23 minutes following the onset of the convulsion. There were no after-effects It is interesting to note that a convulsion occurred two minutes after intravenous injection of metrazol In the light of recent experimentation with metrazol in the production of convulsions in cases of dementia praecox,¹⁹ we are led to the conclusion that

metrazol may have been the causative factor of the convulsion in this case

Case 6. A. W., age 33 negro male. Operation for lobectomy. Anesthesia was uneventful and patient was conscious 25 minutes post-operatively. Four minutes later twitching of the right side of the mouth and right eyelid set in and lasted one hour and forty five minutes. Recovery was uneventful. It is interesting to note that following a previous operation for revision of thoracoplasty this patient developed a right facial paralysis on the first postoperative day. It cleared up entirely and it was thought that he had had a cerebral thrombus that had been absorbed.

Case 7. A. S., age 20 white male. First stage thoracoplasty. Eight minutes following the completion of an uneventful anesthesia we noticed twitching and a droop of the right side of the mouth with occasional shaking of the head from side to side. Eight minutes later he answered questions by nodding his head and four minutes following this he was fully conscious and able to talk. He complained of right-sided headache. Superficial neurologic examination revealed a suggestive left-ankle clonus. Thirty five minutes following the onset, all symptoms had cleared. Uneventful recovery.

Case 8. A. J., age 37 negro female. Eleven minutes following an induction during which the patient coughed spasmodically and respirations were jerky and shallow carpopedal convulsive spasms ensued. Oxygen was given and the spasms ceased in about one minute. There were no further untoward manifestations. We believe these muscular spasms were a manifestation of

an anoxic state resulting from the insufficient respiratory exchange during induction.

In our previous experiences with other anesthetic agents, such as nitrous oxide oxygen-ether, avertin nitrous oxide-oxygen, evipal and local and paravertebral, embracing over 1,000 administrations for thoracic surgery, we had only 1 patient that developed convulsions during anesthesia with nitrous oxide. This case proved fatal. With 300 cases of cyclopropane anesthesia for thoracic surgery, we had 8 cases of muscular twitchings or convulsions with 3 deaths. In view of our experience, we must conclude that cyclopropane is a contributory factor in the production of convulsions. For the pathogenesis of these convulsions different theories have been proposed, but none seems completely satisfactory.

Mortality—In Table 3 we have recorded all the deaths in the thoracic surgery series that occurred within thirty days of operation, no matter what the cause. In 1 case death occurred following induction before operation. Table 4 includes the deaths in our nonthoracic series of operations occurring within seven weeks of operation. We have included the postmortem findings when available. (See page 532 for Table 4.)

Other Anesthetics

Table 5 is a study of results with various anesthetic agents we have used for thoracic surgery

(1) Nitrous oxide necessitates high concentrations to produce relaxation, therefore not sufficient oxygen is available to the pulmonary ventilation Cyanosis is a prominent feature in a large percentage of cases Other disadvantages include struggling during induction, marked increase in the pulse rate, and deep, forceful respirations Postoperative restlessness was less marked with nitrous oxide and, with the exception of evipal, fewer patients were in shock at the end of the operation with this agent than with the others

(2) Avertin (tribromethanol) was used in 226 cases The average dose we used was 60 to 80 mg per kilogram With avertin as a basal anesthetic, a greater proportion of oxygen could be administered in the supplementary gas-oxygen mixture Another advantage is the smooth induction However, the dis-

advantages offset the advantages Shortly after induction, respiration becomes very shallow, and sometimes almost imperceptible, and cyanosis ensues in a large percentage of cases Postoperatively the patient is drowsy, respirations are shallow, cyanosis is present, and the cough reflex is depressed for hours Contralateral spread of the disease occurred postoperatively in 11 cases (49 per cent), 6 of these cleared, the other 5 terminated in death This complication occurred with avertin much more frequently than it did with any of the other anesthetic agents we used There were 2 deaths due to avertin shock Another case of shock that did not terminate fatally is worthy of mention

This patient, a 31-year-old white female, was given 80 mg per kilogram of avertin for a second stage thoracoplasty Five weeks previous to this, she had undergone a first stage thoracoplasty, avertin (80 mg per kilogram) and gas-oxygen had been administered with no untoward effects At the time of the second administra-

tion, there were no unusual manifestations until one to two minutes following induction with gas oxygen. Suddenly the patient lapsed into deep shock with very slow respirations accompanied by cyanosis. Stimulants were given, but 30 minutes later respirations ceased. Mouth-to-mouth insufflations and manual artificial respiration were instituted. Shortly thereafter the heart ceased to beat. Adrenalin (20 minims) was injected intracardially, immediately the heart began to beat strongly and soon respirations resumed. Further stimulants were given and consciousness returned four hours and fifteen minutes following the onset of shock. She was extremely restless and vomited several times that night. She was disoriented hysterical, and had a bilateral Babinski, numbness of the left thumb and a left lateral nystagmus. She lapsed into a cataleptic state. Spinal fluid was negative. These symptoms lasted for ten weeks, at the end of which time her mental state was normal and all abnormal neurologic signs had disappeared. We do not believe that these symptoms can be attributed to avertin.

(8) Evipal. The results we obtained with 300 cases of evipal anesthesia have appeared in two previous articles.^{12,20} In Table 5 are recorded the results obtained with 605 administrations which were given from August, 1934, to September, 1936. It will be noted that there is an average drop in systolic blood pressure of 40 mm. of mercury and a marked

rise in pulse rate. There were 11 cases (1.8 per cent) that developed apnea shortly following the injection of evipal. Respiration in all of these cases returned to normal after resuscitative measures had been instituted. Postoperative shock occurred in a much smaller proportion of cases (13.9 per cent) than with any of the other anesthetic agents. In contradistinction to avertin, postoperative exudative spread occurred in only 4 cases (0.7 per cent), 3 of whom died later. In the other, the disease was reabsorbed.

(4) Local and paravertebral anesthesia was used in 27 cases. These were selected cases that we deemed poor risks for general anesthesia. Pain during operation was complained of in 10 cases, and in 1 of these it was necessary to supplement with gas-oxygen. Cyanosis during operation occurred in 6 cases and it was necessary to administer carbon dioxide oxygen to all of these. There was one case of novocaine shock. 23 minutes following the injection of 1 per cent novocaine (8 ounces) respiration was shallow, the blood pressure could not be recorded and the patient did not respond to external stimulation. The operation was postponed and stimulants given. In a short time, respirations became normal.

and the blood pressure rose to the pre-operative level. We believe that our series of cases is too small to draw any definite conclusions as to the advantages of local and paravertebral anesthesia for thoracic surgery. However, we have noted that postoperatively the patients are much brighter and that they seem to run a smoother postoperative course than those undergoing general anesthesia.

General Results of All Anesthetics in Thoracic Cases

(1) *Mortality*—In Table 6 are recorded all deaths with the various anesthetic agents, the time and cause of death are included. It will be seen that the greatest mortality (8.4 per cent) followed avertin anesthesia and the least (6.4 per cent), evipal anesthesia, whereas the mortality percentages following cyclopropane, nitrous oxide, and local and paravertebral differed only very slightly.

(2) *Morbidity*—Schmidt and Waters,¹³ in their review of 2,200 cases of cyclopropane anesthesia, found fewer respiratory complications with this gas than with others. In our series postoperative respiratory complications occurred in 3.7 per cent of the cyclopropane anesthetics, 5.2 per cent with nitrous oxide, 6.6 per cent with avertin, 2.3 per cent with evipal, and in none of the local and paravertebral cases.

Conclusions

The results obtained with different anesthetics in thoracic surgery have been presented. Almost all the patients undergoing thoracic surgery had chronic pulmonary tuberculosis, of these 70 per cent had bilateral disease.

Our results with cyclopropane anesthesia are presented in detail. For comparison, we included 100 cases which had other than thoracic operations, but who were anesthetized with cyclopropane. Convulsions and muscular twitchings as a complication of cyclopropane anesthesia for thoracic surgery occurred in 8 patients. We had no convulsions

in the nonthoracic series. In our previous experience in chest surgery with other anesthetic agents, we had only 1 case of convulsions.

Of the 1,370 thoracic cases studied and analyzed, cyclopropane anesthesia was used in 300 cases, gas-oxygen in 212, avertin in 226, and evipal in 605. Local and paravertebral anesthesia was used in 27 selected cases. A detailed report of our results with these various agents is given, and a study of the morbidity and mortality rates is included.

We wish to express our appreciation and gratitude to Miss Mary Norton, Records Librarian, and her staff for their co-operation.

PREVENTION OF MATERNAL DEATHS

CHARLES A. GORDON, M D , F.A C S , Brooklyn, New York

MATERNAL welfare has to do with the well being of mothers, their social and economic condition, their willingness as well as their physical capacity to bear children—a full family life. No matter how perfect, preparation falls short if the end result of labor is stillbirth or neonatal death.

It has to do with the whole concept of preventive medicine, which, though not built around obstetrics, might very well be so far as mothers are concerned. Not a simple problem at all, their health truly depends upon environment, death often harks back to the rickets of infancy, the rheumatism of childhood, and the dysfunctions of youth. The skill and experience of the obstetrician is an important factor in the prevention of maternal death, yet women who are barely able to eke out a living, willing to exchange food and rest for the clothes and diversion they desire so much—women who rarely see the sun, overtired and overconscious of the stress of life, are not good subjects for parturition. The changes associated with the vastly accelerated speed of modern life have been gradual somewhat vague it is true, difficult of appraisal, but none the less real. More and more, simple failure of the forces of labor simulates disproportion, and women who should have normal labor delay so long that intervention becomes necessary. It is certain that childbirth has become more difficult.

Too long birth has been looked upon as a simple physiologic process which may become pathologic it is true, yet remain a safe undertaking. No function of the human body is ever subjected to a stress at all comparable with parturition, even in its simplest form, childbirth is never free of danger. Told that complications are preventable, women expect

none. This time-worn platitude should be summarily discarded, and women told that most of their hazards may be foreseen and controlled. That is quite different.

There has been considerable decline in maternal mortality in the last ten years. The trend is downward. That childbirth has actually become safer may deserve no emphasis by governmental agencies—certainly it has had none. For some reason, it has seemed better to say that in 1936 there were more than 14,000 deaths of women associated with pregnancy or childbirth than to point out that there were but 12,182 puerperal deaths in 1936, or 362 less than in 1935. Would it not be better to say that child birth ranks third as a cause of death in women between the ages of 15 and 45? We are told that ten million people in the United States live more than thirty miles from an approved hospital but it is a fact that only about 1 per cent of births were unattended.

It should be clearly understood that the maternal mortality rate shows the number of maternal deaths in relation to live births, deaths from ectopic, abortion, and many general causes are included. Acute respiratory diseases may seriously affect these figures, for deaths from influenza and bronchopneumonia, with intercurrent abortion or labor or even pregnancy undelivered, are assigned to the maternal mortality column, even lobar pneumonia, unless its time relationship to the puerperal state is clearly stated on the certificate, meets the same fate. This method satisfies the statistician very well, but the obstetrician not at all. Contraception abortions increasing by tens of thousands, a higher proportion of primiparas, and the growing age of primiparity itself must be taken into account.

*Read at the Annual Meeting of the Medical Society of the State of New York
New York City May 10 1938*

when comparisons are made with older figures. Improvement in mortality rates is more real than apparent.

International comparisons are particularly futile. Propagandists love to tell us that the United States has the highest rate, yet it has been shown that if international assignment of puerperal and nonpuerperal causes were uniform, our place would be fifth from the highest. No doubt it would be better still, if major factors like race, age, and parity, urbanization and relative incidence of acute respiratory infection had been given any consideration. Furthermore, all statistics depend upon the accuracy of the original record, and comparability can be questioned until we can more honestly evaluate the importance of the contributory causes of death. The arbitrary method of the "Manual of Joint Causes of Death" is not satisfactory. It is obviously unfair to infer that the quality of medical care is inferior in the United States. Such propaganda is demoralizing, tends to increase fear, and is of itself a cause of mortality.

Obstetricians have shown that the only effective method of analysis is by their own critical review of the actual certificates of death in co-operation with local health departments and the physicians concerned. This has been done so well in many communities that now we are repeatedly told that one-half to two-thirds of all maternal deaths are preventable.

A very large proportion of these deaths is inevitable. In our zeal some of us have gone too far in assessing preventability. Perhaps it would be better to discuss deaths as associated with controllable causes. Certainly it is impossible to define preventability exactly. Antepartum hemorrhage cannot be prevented nor will good management ensure safe delivery. Placenta praevia and abruptio are formidable complications which tax the skill of the most expert obstetrician. Even the less common presentations of the fetus increase maternal as well as fetal mortality. Eclampsia may occur in spite of excellent antepartum super-

vision. The diagnosis of moderate disproportion is not simple, and its management, whether by trial labor or test, difficult forceps or easier cesarean, involves considerable risk. The skill and judgment required for operative delivery are just as necessary when we allow women to remain long in labor with the hope of avoiding intervention. That our decisions are often reached under pressure of very trying circumstances unfortunately receives little attention in reports.

Certainly the majority of deaths from intentional abortion are beyond our control. The majority of abortions are induced, yet only the mortality of proved criminal abortion is assigned to homicide in our statistics. Taussig estimates that nearly 700,000 abortions occur every year in this country, that 60 per cent of them are induced in women who are unaware or careless of the risk. Abortion accounts for one-quarter of all our maternal deaths, nearly half of the deaths from septicemia, the greatest cause. These are the figures which need publicity, one good reason why the death rate from sepsis has not yielded. Their importance cannot be overemphasized, for thousands who recover pay their pelvic debt later in ectopic, placenta praevia, accreta, abruptio, sterility, and more abortions. Women contribute voluntarily to their own death rate. There is very little that we can do about it except to await public education which is sadly needed. In the meantime it is well to remember that even therapeutic abortion, an operation which is intended to save life, carries with it its own mortality. It would be best to consider all incomplete abortions potentially septic, advise hospital treatment in all cases with any untoward symptoms, and weigh well the risk of simple curettage.

Though puerperal infection is largely associated with operative interference, the problem is not as simple as it would appear. It is difficult to trace infection to its source. In the majority of instances it is introduced during examination or operation, but often delivery has

been spontaneous, and there has been no examination whatever. Recent investigations, however, have shown that autogenous infection is not an important cause. Casual streptococci in the throats of attendants are not very harmful, but carriers who have not fully recovered from acute respiratory infections, those with coughs, colds, and hoarseness, are very dangerous, whether attendants, relatives, or other visitors. Mild forms are common and the clinical course of the fever depends upon virulence of the organism and resistance of the patient. No perfect antiseptic is available, and treatment is largely symptomatic. Though often ineffective, preventive measures are highly desirable. Those new amendments to the Sanitary Code of the City of New York which make limitation of visitors and general use of masks compulsory in every lyng in institution in the city, might well be adopted everywhere.

I would not have you think for a moment that I look upon the situation with satisfaction, or that we have reached that irreducible minimum which we feel sure exists. Not at all. The death rate would fall at once if all the factors could be controlled. It is not alarming, however, and obviously no spectacular solution of the problem is possible. Tax-paid medicine is certainly not the answer.

Education is the key to the problem, but of necessity it is time-consuming and difficult. In spite of great national effort the gospel of prenatal care has not fully reached the public. At any rate, a great many women pay no attention to it, even those who have had repeated dystocia. We agree on the advantages of good antepartum care, yet probably half of our maternal deaths occur in women who have had no examination or advice of any kind from a physician during pregnancy. There is good reason to believe, however, that we are at fault too. For nearly half of those who do register with a physician receive inadequate or poor care. There can be no excuse for this.

About half of our puerperal deaths are preceded by an operation like forceps

dilatation of the cervix, manual removal of the placenta, version, extraction, or cesarean. Often the physician has not seen the patient until an emergency has arisen, yet we are not without blame in this matter. Even the experienced general practitioner needs help in the management of eclampsia and the hemorrhages of pregnancy. Forceps and version are not for the novice, nor should cesarean be done by the inexperienced or the interested at-the-moment surgeon, no matter how skillful he may be, for the risk is so great that all indications for the operation should be subjected to the closest scrutiny. Even in the perfect case danger of death from peritonitis or anesthesia cannot be eliminated. The lower segment operation and radical cesarean carry no assurance of safety, even if there is no evidence of infection present. Mortality in all types of operation depends upon the same factors. The tremendous contribution made by cesarean section to our mortality figures is a cause of grave concern.

Less operations would appear to be the answer, yet women ask that labor be shortened and the pains lessened. And so would the most conservative among us, even though we had made up our minds to use better judgment. Obstetricians know that normal labor cannot be improved upon, yet a strong movement for more or less radical obstetrics has thoroughly involved the entire profession. Many who are extraordinarily well qualified to give women what they desire, have imparted their views to the multitude, but unfortunately not their skill. Whether we are conservative minded or not, whether we call this meddling midwifery, as some do, or not, makes very little difference at present. We must cope with the situation as we find it. It is likely that this modern idea has come to stay, and it is at least doubtful if many of us will be willing to force our patients to accept the hard way. Aside from analgesia, anesthesia itself is clearly a definite hazard. Clearly only those who have been well trained in these new methods should practice them.

Hospitals admit a steadily increasing number of women for delivery. In 1936, 71 per cent of all births in urban areas occurred in hospitals, while in rural areas only 14 per cent were institutional. In 1937 in New York City, 89 per cent of all women were delivered in the hospital. Our maternal mortality rate is 36 per cent higher in urban districts, yet it has been found impossible to calculate rates comparing delivery in the hospital with the home. The comfort and advantages of the hospital should be obvious, yet some have said that, since interference may be easier there, home delivery should be encouraged. At any rate this is no time to discuss that question, for hospitalization is steadily increasing. We are confronted with a fact, not a theory, and this very definite trend should be recognized by public-health authorities. It would certainly seem better to bring patients to a well-equipped center than to send public-health nurses out to them.

Every hospital should be a safe place for delivery. That is what every woman has a right to expect, the best interests of all concerned demand it. Large or small, the hospital has very positive obligations. It must control and closely supervise its obstetrics, for responsibility for the patients' welfare does not rest entirely with the physician. Nothing need be done to discourage that intimate relationship between patient and physician which is so essential, yet the patient must be protected and the physician supported whether they wish it or not. Facilities must be mobilized for advice and help, and consultation must be easily obtained when indicated. Not only should general practitioners be afforded opportunities to do good work, but they must be made to feel that they are an important part of the obstetrical service in the hospital.

Since obstetrics is an art, it will never be possible to teach more than obstetrical catechism in the medical school. No revision of the undergraduate curriculum will ever do more than train the student in the management of normal cases. There is neither time nor opportunity

to teach that which must be learned by practice—not precept. The young graduate has been largely left to his own resources, forced to grow in experience and judgment under the spur of necessity and expediency. When the intern years become a more definite part of the medical curriculum, some progress will be made.

Postgraduate education is the master key to happier results. The problem will be solved only when the education of everyone who practices obstetrics is made continuous. Not by refresher courses and lectures which, though desirable, are not very effective. Not by insisting that the general practitioner take postgraduate courses, for he will not, nor can he get what he needs. Not by belaboring him with statistics, or viewing with alarm preventability percentages, but by providing for him wide opportunities for easy continuous contact with the form and substance of good obstetrics in well-staffed hospitals. These institutions need have no fear for their own results, for properly controlled and supervised the average man is an excellent practitioner of midwifery.

If you think this Utopian, though I maintain it is not, we have, in the committee on analysis of maternal deaths, another perhaps more quickly available method of education. In many of our large cities committees of obstetricians have provided us with comparable statistics and conclusions, which they have arrived at after searching examination of the circumstances surrounding every maternal death in their own communities. The high educational value of their discussions, however, has been, for the most part, completely overlooked, for comparatively few have taken part in these committee deliberations. Many of us have become maternal-mortality conscious, and we have been made aware that a great many maternal deaths are preventable, yet individual interest on a large scale must be excited, and every physician made to feel that he himself can make an important contribution. This is essential. If inquiry, discussion, and

investigation are the basis of the modern synthesis of education, the committee on analysis will provide us with a nearly perfect mechanism

Review committees, consisting of physicians representing every hospital which admits women for delivery, ectopic, and abortion, should be set up everywhere by county medical societies. It is important that hospitals be invited to name their own representatives, the society appointing members to inquire into home delivery. Local health officers will be more than willing to provide transcripts of the certificates of death. With this basic material, all the pertinent facts and circumstances will be minutely explored by that member to whom it may be properly assigned for inquiry, and recorded in detail. When the committee meets, which will be as often as is necessary to suit local conditions, all deaths are examined, and all controllable factors developed by wide-open discussion. Hospitals or individuals should not be identified, their names being known only to the recorder or secretary of the committee, who reports the case for consideration. To arouse vigorous discussion it is best to assign responsibility, but percentages quickly arrived at need not find publication.

No criteria for preventability need be set up other than those which occur about the case material. Conscience will grow with consciousness of individual responsibility. For continued education, group discussion of personal experience is better than the scientific address and the symposium. If county organization is not always practicable, adjacent counties

may operate jointly. If well-qualified obstetricians are not available, consultants provided by a state medical society or some other agency may attend the meetings.

This method of approach to the problem has been highly developed in Brooklyn. Attendance is excellent, interest high and steadily growing. Forty-eight hospitals have co-operated perfectly in the analysis of maternal deaths. A card of admission is required since none but physicians may participate. Perfect anonymity has overcome all possible objections. Specialist and general practitioner have profited alike. Abortion, ectopic, cesarean, hemorrhage, toxemia—all the causes of death in the rubrics, have been repeatedly discussed as actual cases with their practical implications. Nor has the widespread knowledge that every maternal death in Brooklyn is closely scrutinized done any harm.

The medical profession is keenly interested in this problem and aware of its responsibility in the training of physicians. Education of the public, no less important, is a tremendous task which calls for more thoroughly organized effort than we are able to carry on ourselves. In the face of severe social and economic maladjustment, for which we certainly are not responsible thousands of women far and wide throughout the nation have been taken care of in childbirth by physicians with no thought whatever of their own economic problem. We are doing more than discuss the problem, for childbirth has become safer.

250 Jefferson Avenue

"The most dangerous period in an individual's life is during the first twenty-four hours after birth," said Dame Louise McIlroy in a recent speech. Aren't the last twenty-four a bit risky?
—Punch.

Alcoholic intoxication is a predisposing cause of pneumonia and the death rate in pneumonia in alcoholic addicts is definitely higher than that of abstainers from alcohol. The *J.A.M.A.* says in an editorial.

TREATMENT OF LOBAR PNEUMONIA WITH SULFAPYRIDINE

W L WHITTEMORE, M D , F A C P , C L ROYSTER, M D , and
PAUL A RIEDEL, Ph D , New York City

(From the New York City Hospital, Welfare Island)

THROUGH the courtesy of the manufacturer in supplying a quantity of sulfapyridine, an opportunity was afforded us to study further the action of this drug at City Hospital, New York City. With this supply an attempt was made to evaluate the effects of sulfapyridine in lobar pneumonia. Observations were made concerning dosage, blood concentration of the drug, therapeutic response and untoward reactions when these occurred.

Our series of cases comprises 30 unselected patients, with pneumococcus lobar pneumonia, treated in the wards of City Hospital between January 1, and February 25, 1939. The age of the patients treated varied between 15 and 75 years, with an average age of 36 years. There were 20 males and 10 females. Twenty-three of the patients presented no evidence of complicating illness on admission. The complications found are listed: (1) 1 patient, seven months pregnant, who had a premature labor during the course of her Type III pneumonia, (2) 2 rheumatic cardiacs, in one of whom the process was inactive and in the other the process was questionably active, (3) 1 patient with aortic aneurism and luetic heart disease, (4) 2 patients with hypertensive and arteriosclerotic heart disease, one of whom had severe heart failure, (5) 1 with beginning empyema and bacteremia, Type I, admitted on the seventh day of illness.

The history of illness on admission varied from four hours to seven days. The average of all was three days. The types of pneumococcus encountered were

| | |
|----------|-------------|
| Type I | 10 patients |
| Type II | 1 patient |
| Type III | 4 patients |
| Type V | 1 patient |

| | |
|------------|------------|
| Type VII | 2 patients |
| Type XII | 1 patient |
| Type XIV | 1 patient |
| Type XVI | 1 patient |
| Type XVIII | 2 patients |
| Type XXXII | 1 patient |

In planning the administration of the drug we referred ourselves to the plan followed by Evans and Gaisford, who suggested the following dosage: "One tablet four-hourly for three to four days, followed by 1 tablet twice daily for a further two or three days, giving an average total of 12 grams. Later, it was decided to administer large doses during the seventy-two hours immediately following the admission, the routine being to give 2 grams statim, and 1 gram four-hourly thereafter, making an average total intake in the later cases of about 25 grams."*

The dosage used in the treatment of our first 8 cases closely followed this routine. On admission, the patients were given sulfapyridine by mouth in doses of 1 gram every four hours for two days. This was then reduced to 1 gram every six hours for two days, and then 1 gram every eight hours for two days. Later in our series, 2 grams were given initially, followed by 1 gram every four hours for seven days.

Our study of these patients comprises in all, a determination of blood levels, free and total sulfapyridine, blood cultures, sputum typing, blood counts, icteric indices, x-ray examination of the chest, routine and microscopic examination of urine, Wassermann reaction and blood chemistry, and, in some cases, sedimentation rates. In estimating the blood levels of the drug, readings were taken at the end of twelve, twenty-four, forty-eight,

* Evans and Gaisford (London Lancet, July 2 1938.)

ninety six, and one hundred and forty-four hours

The method used in the determination of the total and free sulfapyridine was that described by Marshall. In short, it consists of the deproteinization of the blood with *p*-toluene sulfonic acid. Marshall used saponin solution to hemolyze the blood but this was omitted and distilled water substituted. Two filtrations were found necessary to obtain a clear filtrate. For the determination of the free sulfapyridine, a measured amount of the filtrate was diazotized with sodium nitrite and a color developed with an alcoholic solution of dimethylnapthyl amine. For the determination of the total sulfapyridine a measured amount of the filtrate was hydrolyzed by placing it in a boiling water bath. It was then cooled and diazotized and coupled in the same manner as in the determination of the free sulfapyridine. It was found that it was essential to keep all the reagents at icebox temperature to avoid decomposition.

The total dosage in our first group of 8 patients varied from 16 to 34 grams, and was continued to 50 grams in one instance. On this regime an average drop in temperature to 101 F from an average of 103½ F was observed in twelve to twenty four hours, and down to between 99 and 100 F at the end of forty-eight hours, with marked signs of clinical improvement, decreased toxicity and pulse rate. Subjective response was equally marked, many of the patients feeling so well that they wanted to be up and about. Cyanosis decreased as rapidly as did dyspnea, although the actual respiratory rate frequently remained rapid until signs of resolution occurred. This took place around the fourth or fifth day of treatment corresponding to the average time for this phenomenon in pneumonias treated with other methods. Methylene blue was not used in any of our cases. All of these patients, except 1 who developed further involvement on the fourth day with marked nervous system depression, bilateral papilloedema, and pronounced personality changes proceeded

to convalesce uneventfully, but continued to maintain temperatures of 100 F to 100.5 F up to the sixth or seventh day of treatment. By the seventh day all of this group had a normal temperature except the 1 patient noted above.

Hepatitis has been mentioned as a complication and so icteric indices were recorded before the drug was administered and repeated at frequent intervals. This was done in an endeavor to determine if liver damage was increased or produced by the drug. It was noted that in 7 of the 8 cases the icteric index decreased during treatment. Nausea and vomiting were present in only 2 of the patients and in none was any dose missed or lost because of this reaction. No other complications or side reactions were noted.

This incidence of nausea and vomiting seems to be much smaller than has been recorded by other observers, or noted by us subsequently when our dosage was increased. We found that the blood concentration, as has been confirmed by others, varied greatly, the total amount of free and combined sulfapyridine ranging from 0.7 to 3.5 mg per cent. In spite of this variation in concentration, there was a uniform clinical response to a constant dose of the drug, with the exception of the 1 patient noted who developed a spread of his disease.

In perusing the current literature we find Flippin, *et al** noted, "There was a great variability in the concentration of free sulfapyridine among individuals receiving the same dose schedule. The lowest estimate was 1 mg per 100 cc, and the highest was 18 mg." Although our highest reading reached only one third of this highest figure, the variation still was marked. Flippin, *et al* also noted, "Many patients with blood levels which apparently remained below 3 mg per 100 cc. enjoyed satisfactory recoveries from pneumonia. The blood levels in 3 of the patients who died were 12, 1.5, and 5 mg, respectively, per 100 cubic centimeters." It was not felt that in any of the patients of our first group an inadequate dose of the drug was given and our

* J.A.M.A., Feb. 11 1939

FIG 1 Composite Temperature Curve

FIG 2 Blood Concentration Curve

findings are in agreement with Flippin's findings

Figure 1 indicates the typical response to sulfapyridine therapy and is a composite grouping of the temperatures of our 30 patients. The dose of the drug for 22 patients varied from 21 to 40 grams. The average was 30 grams. The total blood levels in this group varied from 3.5 to 7.2, and the free varied from 2.5 to 6.4 mg per 100 cc.

We noted a secondary rise in temperature in the first group of cases after the initial drop and, for that reason, the subsequent 22 were given larger doses of sulfapyridine in the hope of eliminating this low-grade secondary rise. These patients received an initial dose of 2 grams and then 1 gram every four hours for seven days.

The clinical results in this group closely approximated those in the 8 previously considered with the secondary rise still present, unaffected by the increased dosage. In considering the possible causes of this, it was noted that P. H.

Long, in 1937, stated that neoprontosil in a single dose of 100 cc of a 2.5 per cent solution administered subcutaneously, or in repeated small doses might produce fever. We offer no explanation at this time, nor have we found this important, though 1 patient did exhibit a sharp forty-eight-hour febrile reaction to 106 F with delirium. His abrupt second drop on discontinuing the drug was followed by normal temperature and normal clinical course. Vomiting was noted in this patient before administration of the drug. In contrast to the infrequency of nausea and vomiting in the lower dosage group, we encountered marked gastric disturbance in 14 of the 22 in the higher dosage group. In persisting with the treatment, save in 2 exceptions, we found that the nausea and vomiting ceased.

Complications—From this group of 30 patients, 1 patient aged 76 with hypertensive and arteriosclerotic heart disease died. She was a Type XII, right lower lobe pneumonia with a history of head injury followed by signs of concussion.

TABLE I—SECONDARY RISE—TEMPERATURE CURVE

| RETURNED TO NORMAL | REMAINED NORMAL | TEMP TO 4TH DAY | TEMP TO 5TH DAY | TEMP TO 6TH DAY | TEMP TO 7TH DAY | TEMP TO 8TH DAY | BEYOND 8TH DAY |
|--------------------|--------------------|-----------------|-----------------|-----------------|-----------------|-----------------|----------------|
| 24 hrs 3 | 2 | | | | 1 | | |
| 48 hrs 14 | 6 | 1 | 2 | 1 | 1 | 1 | 2 (1 empyema) |
| 72 hrs 6 | 3 | | 1 death | | | | 1 (extension) |
| 96 hrs 3 | 1 | | | | 1 | | 1 (extension) |
| 5 days 1 | 1 | | | | | | |
| 7 days 1 | 1 | | | | | | |
| 8 days 1 | 1 | | | | | | |
| | 15 | 1 | 3 | 1 | 3 | 2 | 4 |
| 14 days 1 | Hemolytic jaundice | | | | | | |

10 days previous to admission X-ray diagnosis was confirmatory of her pneumonia. She appeared to be recovering from her pneumonia when she suddenly went into a coma and died.

Three patients (2 in the higher dosage group) when apparently recovering had an extension of their pneumonia necessitating a second course of treatment.

One patient (in the higher dosage group) who two years previously had had intensive arsenical therapy for syphilis, had the usual initial drop, then became jaundiced (icteric index, 40), developed a large liver and spleen with secondary anemia, and ran a febrile course for another 14 days before entering normal convalescence. He had received 9 grams of sulfapyridine before this was noted. One patient was admitted on the tenth day of illness with a Type I pneumonia of the entire right lung. A Type I bacteriemia was present and signs of fluid were present. He had the usual initial response to the drug but on the fourth day became febrile and this con-

tinued until drainage was instituted. A Type I pneumococcus was found in the chest. He had an uneventful recovery.

It was noted that 1 girl with a Type III pneumonia and a Grade I rheumatic heart had a prolonged period of resolution.

One boy with persistent vomiting from onset was given the usual dosage by rectum. His temperature drop occurred in forty-eight hours. It was noted on the fourth day that the drug level in his blood was 3.2 total and 0.8 free.

Summary—Thirty lobar pneumonia patients who had x-ray confirmation of diagnosis, sputum typing (6 of whom were negative), blood cultures, blood counts, total and free sulfapyridine blood level determinations, icteric indices, blood Wassermanns and chemistry, and routine urinalyses, were treated with sulfapyridine. Of the 30 patients, 29 recovered and 1 died. These patients were unselected save for the elimination of several patients admitted who were obviously on the point of recovery. There were no unusual blood-count changes.

NOTICE OF TEMPERATURE SYMPOSIUM

A symposium on 'Temperature and Its Measurement in Science and Industry' will be held under the auspices of the American Institute of Physics, probably next fall the dates to be announced later. Consistent with the title the symposium will broadly cover many fields its primary purposes according to present plans being to (1) co-ordinate the treatment of the subject in the sciences and branches of engineering (2) review principles and bring up to date the record of recent work, (3) accumulate contributions for a comprehensive text to be published as soon as possible after the symposium is held (4) reveal the subject as an important branch of physics and (5) supply schools with the information required for the improvement of curricula. The Institute confidently expects that a stimulating, valuable, and unified program will be arranged an aim which will require the help of many contributors.

A representative steering committee has been formed consisting of the Chairman, C. O. Fairchild, Director of Research, C. J. Tagliabue

Mfg. Co. Dr. E. F. DuBois, Medical Director, Russell Sage Institute of Pathology and Professor of Medicine, Cornell University Medical College. Dr. Gustav Egloff, Director of Research, Universal Oil Products Co. Dr. John Johnston, Director of Research, U. S. Steel Corporation. Dr. Walter G. Whitman, Head, Department of Chemical Engineering, Massachusetts Institute of Technology, and Dr. H. A. Barton, Director, American Institute of Physics.

Those who are interested in taking part in this symposium should communicate with the Institute at an early date, giving information regarding their field of work and the subject of the contribution they wish to make. Such contributions will be co-ordinated with the subjects of a group of invited papers and assignments and divisions made. Further information for contributors will be available shortly.

The History of Syracuse

WITH the arrival of Champlain in the locality, began the history of what is now a prosperous and beautiful city. The hostility of the Indians and the devastation of the French and Indian War of 1744 did not dissuade the settlers from this promising region. The first pioneers to settle permanently were Ephraim Webster in 1786 and Major Danforth two years later.

With the discovery of salt springs, Syracuse's first industry, there was a great increase in the population. The production of salt was its major industry until 1862. Better means of transportation were needed with the growth of the entire area, and in 1817 the Erie Canal was begun—an important factor in the progress of the future city.

The village was incorporated in 1825. The construction of plank roads and stagecoach lines was the beginning of Syracuse as an important rail road center. The first railroad appeared in 1834. The rapidly growing town was merged with Salina and became incorporated as a city in 1844. The city of Syracuse received its name, not only due to the fact that the ancient city of Syracuse had salt springs but also because there was an adjacent town of Salina.

In 1807 Genesee College was brought from Luma, New York, to Syracuse and renamed Syracuse University in 1871. Its first enrollment was 41 students, today it is over 6,000.

The manufacture of salt as a major industry was replaced by many new products of which chemicals, electric washing machines, typewriters, electrical appliances, and air-conditioning appliances are but a few.

Today, Syracuse is a progressive and important city in the heart of upper New York State. The village of 4,000 has become a metropolis of over 200,000. Within the past few years many new improvements have been made to beautify the city. Its parks are numerous and conveniently located. The schools are available to all and the Syracuse Museum of Fine Arts is a center for the study and appreciation of art. It is hoped that the years will bring as many important changes and that the past will be mirrored, magnified many times in Syracuse's future.

Medical Syracuse

THE COLLEGE OF MEDICINE of Syracuse University is the oldest of its colleges. It was founded in 1834 in Geneva, New York, as the Geneva Medical College, and came to Syracuse in 1872, where it became the College of Medicine of Syracuse University. It was located for many years in Orange Street, later McBride Street, where in 1898 a new building was erected. Then in 1937 a magnificent new plant was occupied which had been built in the Yates Castle grounds of the campus of Syracuse University at a cost of \$825,000, modern and complete in every particular. The College of Medicine has always been given highest rating by the Council on Medical Education and Hospitals of the American Medical Association. It is a member of the Association of American Medical Colleges. A matter of historical interest is the fact that it gave the first medical degree to a woman in the United States when it graduated Elizabeth Blackwell in 1847. The College of Medicine has a faculty membership of 215 and a student body of 177. (See page 546 for photograph of the building.)

College of Medicine, Syracuse University

Hospital of The Good Shepherd, Syracuse University

General Hospital of Syracuse

Crouse-Ingving Hospital

Medical Syracuse (Continued)

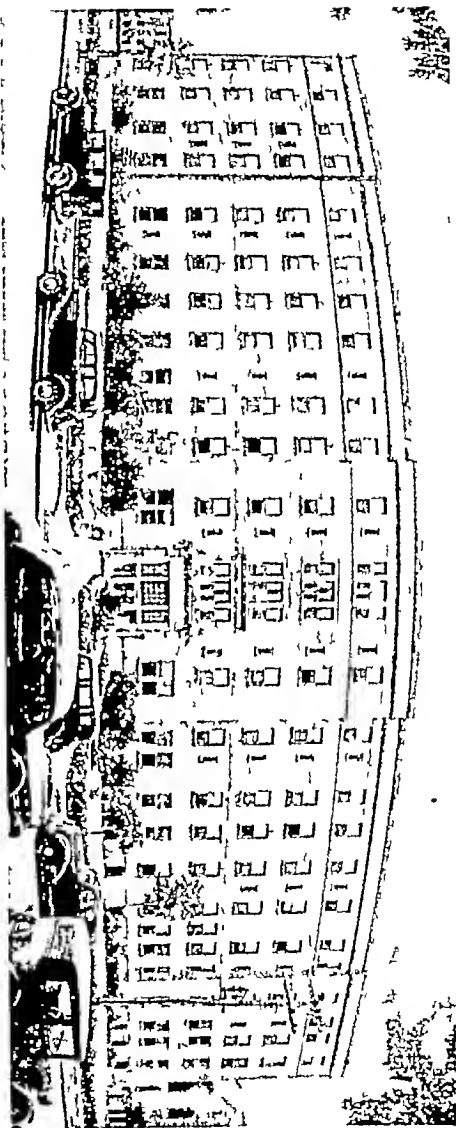

THE SYRACUSE MEMORIAL HOSPITAL was founded in 1887 as "The Syracuse Hospital for Women and Children." It was organized by leading women of the city and is still run by a Board of Trustees consisting entirely of women. Although the original plan was to limit the hospital to obstetric and pediatric service, it has been a general hospital throughout its history. In 1929 the present building was erected through popular subscription. It is one of the most complete and beautiful hospital structures in America. There is a large training school for nurses in the Nurses' Home adjoining the hospital. The bed capacity of the hospital is 250. The obstetric, pediatric, and gynecologic teaching of the College of Medicine is done in these wards.

THE GENERAL HOSPITAL OF SYRACUSE was organized in 1895 as the Syracuse Homeopathic Hospital, but many years ago became a general hospital of both schools. In 1903 it moved to its present location, where it has been entirely rebuilt and now has an excellent modern plant. It has a bed capacity of 110. There is also a School of Nursing.

THE CROUSE-IRVING HOSPITAL was founded in 1912 and has grown rapidly to its present bed capacity of 240. It is well equipped to do work in all fields of medicine. The School of Nursing has eighty pupils and there is a staff of fifty.

THE HOSPITAL OF THE GOOD SHEPHERD, Syracuse University, was organized in 1873 by Bishop F. D. Huntington and the Episcopal Deaconesses and it was used primarily for the care of the aged and indigent sick. In 1885 a Nurses' Training School was established with an enrollment of six students. The hospital has been several times enlarged and improved and now has a great and modern plant. In 1916 it was taken over by Syracuse University and it has since been the chief teaching unit of the College of Medicine. Its Training School is also affiliated with Syracuse University. It has a bed capacity of 280.

Other hospitals and medical institutions of Syracuse are as follows: Syracuse State School for Mental Defectives, 1,068 patients, Onondaga County Sanatorium (Tuberculosis), 255 beds, Onondaga General Hospital, 75 beds, Syracuse Psychopathic Hospital (State), 60 beds, City Hospital for Contagious Diseases, 84 beds, People's Hospital, 43 beds, St. Mary's Maternity Hospital and Infant Asylum, 29 beds.

St. Joseph's Hospital

St. Joseph's Hospital was established in 1870 by Sisters of the Third Order of St. Francis. This was the first hospital in Syracuse. In 1926 the hospital was enlarged to its present capacity of 231. It has a beautiful new plant with complete facilities of a general hospital. The medical and surgical wards are used for teaching purposes of the College of Medicine. There is a Nurses Training School with an enrollment of about sixty.

Annual Reports

MEDICAL SOCIETY OF THE STATE OF NEW YORK

1938-1939

Report of the President

*To the House of Delegates
Gentlemen*

A year ago as President elect in the address customary at such a time, I took up more particularly the necessity for economy. During the ensuing year that necessity has impressed all of us, and, I believe, our definite efforts to be economical, to conserve our resources and to preserve our savings will be appreciated.

While I did not make any definite recommendations at that time, I did state that it was my opinion that the new form of government which had been set up was capable of development into a good and consistent form of control. I am committed to the idea and I believe that a Council composed of men selected on the basis of fitness and availability, which is self-continuing and has general broad policies capable of normal, conservative growth, can direct the business of the Society in a satisfactory and consistent manner. It has the elasticity necessary for its own preservation. It has the firmness requisite for a definite policy. It has the continuity so valuable in making our work run smoothly. It can be modified when you in your wisdom direct it without destroying its usefulness.

This year has been a busy one. The committees have worked well, the harmonious action of the Council in important matters has been noteworthy, and we all have a better understanding of what we should do and how we should do it than we had a year ago.

It is with the highest respect that I commend my associates for their judgments based on experience and for the way in which they have served us at considerable sacrifice to themselves for the good of all. There is no occasion to single out any committee or individual for special commendation, rather would I speak now gratefully and appreciatively of each of them. Their work is described in the report of the Council. It need not be repeated here. It is of the new things that I may speak briefly because you are not acquainted with them as you will come to be as the future unfolds.

The launching of the *New York State Journal of Medicine* under our own control and management has been accomplished. The selection of a Publication Committee, the setting up of the management of our JOURNAL and the merging of this work with that of the Public Relations Bureau, and the management of the exhibits according to your instructions was no small matter. This work requires judgment and experience. We are fortunate that we had within the Society men who were by training and inclination suited to that work. They had the judgment and they had experience. The result is a JOURNAL that is a credit to the Society and will spread our fame. It will stand as long as we preserve our faith in ourselves and in the capability of expressing our own ideas.

The Public Relations Bureau has not lost its identity as a bureau, but the work is administered through the committee

as a whole and each member is familiar, or is familiarizing himself, with this branch of our activities. It is a union of similar interests to their mutual advantage. It will save expense.

I am sure you like the JOURNAL in its new dress and format. It will steadily grow and improve as it fully settles in its stride and has had time to grow to suit its clothes.

This is a momentous year in medicine. Many things have transpired and are to transpire. We have been harassed, besmirched, but it has made us strong. It has united medicine by welding its parts. Men of science and thoughtfulness generally look askance at what has been done to us, sympathize with us, support us. We have been stimulated and our ideas clarified by the injustices which we have suffered. Let us never be downhearted. Let us look with hope and trustfulness on the future which shows the streaks and highlights of the dawn of reason.

It will require many years to evaluate things and bring us to a clear understanding of what we have been trying to do and how honestly we have been doing it.

During this period of tribulation which has involved everybody to varying degrees, engineers have not chosen the engineering projects, economists have not directed the economic activities, and finances have not been controlled by watchdogs of the treasury. Those who believe in thrift and that one of the rewards of labor is the pride of accomplishment have not had much to say about it, politics has, of course, permeated all of the fantastic schemes in new and strange ways, and all scientific attainment has been more or less discredited by one group or another. The science and art of medicine have suffered very definitely along with all other scientific groups through the combined or mass attack by what is really a heterogeneous array of critics ranging from the fatuous to the atrocious.

We have now reached a phase in which Congress is really turning a little toward

economy, the former Director of the WPA expresses disapproval of acts which brought relief into politics and vote-getting, the Secretary of the Treasury doubts whether the processing tax really helps the farmer and that it is a very poor system of taxation anyway, non-medical science as a whole stands firmly with us in the attacks on medicine both as a science and as an art, the President of the United States in a recent message to Congress seems to hope that we are through with panaceas, sound-thinking welfare groups and public-health officials are disinclined to rush onward in the entanglement of private medicine with party politics, and the Governor of the State of New York advises that in at least his state, careful studies be made of insurance plans before hastily conceived laws are passed. Perhaps we may all be thinking more clearly as time goes on and will return to calm straight thinking which will enable us to reason peaceably with one another.

The Interdepartmental Committee reported to a handpicked but ungraded gathering, some of whom were earnest in their wishful thinking, but it included others who by the creation of confusion and the spread of misinformation would destroy democratic principles of government, and only pitifully few who had some conception of what medical care really is. The action of the House of Delegates of the American Medical Association, which met in special session to consider this report, found a controversy by no means insoluble if it were to be taken up in a truly co-operative spirit. Both groups declare that the sick, whether they are indigent, semi-indigent, or able to pay in whole or in part, should receive the best and ever better medical care. There may be disagreement as to the numbers of those who are able to get good medical care and no evidence to show why some of them do not get it when it is available, but that they should have it is sound medicine. There is agreement that tax money should be utilized for public-health projects and for new hospitals and other physical paraphernalia, but

only as the need be shown and only after what is already available has been utilized. In all probability neither group really wants great structures of brick and mortar in the wilderness. The adequate comfortable care of the sick in most instances is a relatively simple, individual problem.

There is agreement that unbudgetable, unpredictable expenses of illness can best be handled by people through some form of insurance. One group would have it compulsory and, of course, paid for by the people whether they want it or not, but the doctors strongly advise a blending of the old relationship so valuable to people when they are sick with the inclusion of insurance in some way or in some such manner that the patient may choose his doctor, his dentist, his nurse, his hospital, things which are very personal matters with most people. His individual rights *must* be respected.

There is much misunderstanding about what socialized medicine really is. Medicine has always been a social agency, one of the most powerful, and by all means the oldest. When Hippocrates wrote a social code for medicine among the Greeks, he, at the same time, wrote of the ancient physicians from which he derived so much knowledge only to transmit it as a "modern" commentator. Socialized medicine is older than history.

Group medicine is not new if by group medicine it be understood as those who created the term understand it, that is, the physicians themselves. Group medicine is joint enterprise of practitioners with various aptitudes practicing medicine as an individual might practice it and utilizing the special aptitudes when, as, and if needed. It is an ethical form of medical practice familiar to all of us. On the other hand, when groups of individuals are treated by contract by a doctor or a group of doctors, it is nothing more than the old lodge practice idea which has been with us but not growing or benefiting the people very much, with a rather poor grade of medicine.

So-called co-operative medicine can be

in the form of co-operative insurance, but when it is in the form of co-operation to hire doctors cheaply it makes for a cheapened imperfect application of medical principles which becomes expensive to the individuals who purchase it.

It would be fine indeed if the era of panaceas for everything could be ended. Medicine has suffered greatly from within as well as from without, over the centuries, because of panaceas. We must resist the temptation to grasp at something as a cure all, as a panacea, as something that will solve the difficulty without further thought or labor. We hear of the great accomplishments of medicine, but medicine itself is cognizant of the great gaps, the great opportunities which may come from filling them, the greater usefulness through a better understanding of things medical by the doctors themselves. It would not pause here with complacency. It has better and greater things to do.

Along with other trained minds, the men of medicine appreciate the value of study and careful planning and they hope to reap benefits through co-operation between various healing and social agencies. It can come only through scientific study and careful planning. It cannot be achieved by the antagonistic attitudes and "smart alec" methods of the loose thinking, quick acting, quack-coddling people who would plan our lives. This is the time of all times when *the scientific method of study should be applied to all our government activities, our social betterments, our ventures into the unknown*.

At this early writing for in order to have the report of the President printed it must be submitted on this 11th day of February, there is no assurance that our troubles are over, no assurance of peace, no promise, if promises are worth anything, that we can safely trust, but there are good omens. Our strength is in our own honesty of purpose. Medicine is a science which recognizes that it can be wrong. It is always self-critical. It has an insatiate avidity for the betterment of mankind. It has striven for it and sacrificed for it down through

the centuries Nothing can exhaust our expectations for better things, better manners of healing, better control of sickness in its many phases and in the prevention of disease It can never be

good enough Nothing must deviate us in our quest for truth

Respectfully submitted,
WILLIAM A GROAT, *President*

March 15, 1939

Report of Secretary

To the House of Delegates

Gentlemen

The administrative year that has passed since your last meeting on May 9-10, 1938, has been an exceptionally busy one for the Society, and the work of the headquarters office has been increased correspondingly The membership has continued to grow Also there has been an unprecedented and rapid succession of events in this country bearing on the social and economic aspects of medicine In many of these matters emergent activity has been needed

Membership—There were elected 1,176 new members in 1938 As shown in the following table, the net change in the total roster as of December 31, 1938, was 648

| | | |
|---|--------|--------|
| Membership—December 31, 1937 | 14,935 | |
| New Members—1938 | 1,176 | |
| Reinstated Members—1938 | 234 | 16,345 |
| Deaths | 180 | |
| Resignations | 86 | 266 |
| | | 16,079 |
| Dropped for nonpayment of dues—December 31, 1938 | 353 | |
| | | 15,726 |
| Elected and reinstated after October 1, 1938, and dues Credited to 1939 | 451 | |
| | | 16,177 |

Honor counties include Chenango, Clinton, Columbia, Cortland, Essex, Fulton, Genesee, Herkimer, Lewis, Orange, Putnam, Rockland, Schoharie, Schuyler, Steuben, Sullivan, Tioga, Tompkins, Washington, and Yates

The comparative totals for the five years 1934 to 1938 follow

| | |
|------|--------|
| 1934 | 13,172 |
| 1935 | 14,064 |
| 1936 | 14,662 |
| 1937 | 15,529 |
| 1938 | 16,177 |

As provided in the Bylaws, the roster of all physicians registered in the state has been kept up to date, adding new names, removing names of those who have died or moved from the state This work proceeds steadily through the year, with greatest pressure on the clerical force when the flow of returning directory cards is at its height soon after they have been mailed to the physicians

In previous years there has always gone with these cards notice of date of appearance of the next edition of the Directory In 1938 no cards were sent out because of the action of the House in postponing publication until the fall of 1939 This year, however, the information is greatly needed to bring the files up to date

Because there will come to the House on April 24, 1939, a recommendation for omitting publication altogether, there has gone this year to the physicians with the usual card the following different notice

Dear Doctor

Kindly fill out the enclosed card or make corrections that may be needed in the data which appeared under your name in the 1938 Medical Directory of New York, New Jersey and Connecticut

Please return at your earliest convenience. This information will be for our files and for use in another edition of the Directory should the Medical Society of the State of New York decide at its next Annual Meeting on April 24 1939 to continue publication

Very truly yours

MEDICAL SOCIETY OF THE STATE OF NEW YORK

In this manner there will be secured the usual information for the files, as required by the Bylaws, without committing the Society one way or another as to publication of a Directory. If the House decides to have a 1939 edition the publication date will not be delayed due to this timely assembly of information

Co-ordination of Activities—The recommendation for a health program made by the Federal Interdepartmental Committee to Coordinate Health and Welfare Activities in July, 1938, started a train of circumstances that has meant a very great deal of work. The action of the Special Session of the House of Delegates of the American Medical Association in September, 1938 (described in the Council Report), brought the Society's nineteen delegates to Chicago. Thereafter the Council took action at several different meetings

The Council's Committee on Public Relations and Economics in its conferences with the State Department of Social Welfare on Medical Relief has stressed the fact that arrangements now to be made for the care of the indigent should be, instead of temporary in nature, definitely permanent and, therefore, beyond any doubt, sound. The State Society's officers have accepted many invitations to address the public at

gatherings interested in "Socialized Medicine" and over the radio. Publicity in the press has been given to these talks, several of them have been printed in various magazines

The production of the JOURNAL from the headquarters office of the Society in all regards excepting printing and mailing has imposed an extra burden which has called for increase of clerical staff and even overtime work. It is obvious that more space will be needed and under instructions of the Council your General Manager has looked over a considerable number of buildings centrally located near the Grand Central Station. Certainly greater efficiency and saving of time could be accomplished by centralizing the different units of the office that are now separated. The Council will be in possession of data for a decision in the near future.

It has been a great satisfaction to take part in the work bearing on public health, malpractice insurance, preparations for the annual meeting, JOURNAL publication, medical publicity, the medical care survey, medical relief, medical expense, and indemnity insurance. It has taken many meetings, some in the office and others through the state, to bring these affairs into shape. Your Secretary wishes to commend the industry, efficiency, and co-operation of the committee members and the officers. He hopes sincerely that his efforts to help have been equally successful

It is a pleasure to register the thanks of the General Manager to the clerical staff for its unfailingly efficient and devoted work under the able supervision of Miss Dougherty. The tradition of many years of meeting extra calls cheerfully, smoothly, and effectually has been maintained

Respectfully submitted,

PETER IRVING, M D, Secretary

Report of the Council

Part I

To the House of Delegates

Gentlemen

Your Council has the honor to report on its administration of the activities of the Society during the period that has passed since your last meeting on May 9-10, 1938. This report will show how your established policies have been carried out and how new situations and matters have been met and studied and the actions taken thereon.

To achieve its purposes the Council has continued the custom of assigning regular duties to small committees which have supervised the work of the Legislative Bureau, the Workmen's Compensation Bureau, the Public Relations Bureau, publications, postgraduate medical education, matters relating to public health, malpractice insurance, and arrangements scientific and otherwise for the annual meeting. It has found it possible to concentrate the work so that the total membership of its working committees has been less than half that of the previous year.

For the committees retained the personnel has been much the same with, however, less need for advisory committees.

Regular meetings have been held on the second Thursday of each month except July and August. One telephonic meeting was found necessary.

The custom has been continued of inviting to the meetings the Second Vice-President, the Vice-Speaker, the Assistant Secretary, the Trustees, the Executive Officer, the Director of the Public Relations Bureau, the Director of the Workmen's Compensation Bureau, and the Legal Counsel. The matters studied and the actions taken are here submitted under subject titles.

In arriving at its decisions in some of these matters the Council found inspiration in the policies set by the House of Delegates of the American Medical As-

sociation at the Special Session held in Chicago on September 16-17, 1938. The Council had requested the nineteen-man delegation from this Society to caucus and elect a chairman who would report back to the Council the action of the Special Session. This was done and the following report went to the members of the Council under date of September 21, 1938, from Dr. Winslow as chairman, and Dr. Irving as secretary of the delegation.

The following delegates and alternate delegates who had been officially designated were all present:

| | |
|--------------------|----------------------|
| Floyd S. Winslow | Samuel J. Kopetzky |
| William D. Johnson | Frederic E. Sondern |
| Thomas P. Farmer | James M. Flynn |
| Edward R. Cunniffe | Thomas A. McGoldrick |
| Grant C. Madill | George M. Fisher |
| Terry M. Townsend | Peter Irving |
| George W. Kosmak | |

| | |
|-----------------------|---------------------------|
| James R. Reuling, Jr. | for (Charles H. Goodrich) |
| Robert F. Barber | (Frederick H. Flaherty) |
| Joseph S. Lawrence | (Thomas H. Cunningham) |

| | |
|---------------------|-----------------------|
| B. Wallace Hamilton | (Carl Boettiger) |
| H. Wolcott Ingham | (James H. Borrell) |
| George A. Newton | (Adolph G. DeSanctis) |

"Dr. Lawrence and Dr. Ingham, who were not on the list of elected alternates, were appointed under the bylaws by the president because the list of alternates was exhausted in the effort to fill these two places.

"The delegation held a caucus at the first recess after the House of Delegates came to order on September 16, with all members present, and in addition by invitation, Dr. Arthur J. Bedell, delegate from the Section on Ophthalmology of the American Medical Association.

"Dr. Floyd S. Winslow was elected chairman of the delegation, Dr. Peter Irving, secretary.

"The House had previously heard addresses by the speaker, Dr. H. H. Shoulders, the president, Dr. Irvin Abell, the president-elect, Dr. Rock Sleyster, and the president of the Board of Trustees, Dr. Arthur W. Booth, which clearly defined the purpose for which the Special Session was called and the unusual importance of the situation.

"Briefly as presented by Dr Booth certain specific proposals (to be embodied later in legislation for submission to Congress) had been formulated by the National Health Conference which met in Washington July 18 19 and 20 1938. The Board of Trustees considered it imperative that the House of Delegates establish a policy relative to these various proposals.

"The proposals fell into the following groups

- 1 Expansion of public health service.
- "2. Increase of hospital facilities
- '3 Medical care for the medically indigent
4. A general program for medical care.
- '5 A program for compulsory sickness

insurance covering the entire population of the United States.

"With the approval of the House a Reference Committee of twenty five was set up. This was divided into five separate sections each one of which considered in detail the lengthy proposals of the Washington Conference under the headings listed above. The five chairmen of these sections or subcommittees were

Walter E Vest of West Virginia
Walter F Donaldson of Pennsylvania
Fred W Rankin of Kentucky
Frederic E. Sondern of New York
Henry A. Luce of Michigan

These five chairmen constituted a guiding committee to receive reports from the five sections and formulate a final report to the House.

'Each of the five subcommittees read its report to the House for discussion and amendment before submission to the guiding committee. The final report of the guiding committee with some few amendments was unanimously adopted by the House.'

There followed in the delegation's report a digest of the action of the Special Session for which there are here substituted the verbatim minutes as printed showing the recommendations that were adopted by the Special Session *

Since it is evident that the physicians of this nation, as represented by the members of this House of Delegates convened in special session favor definite and decisive action now your committee submits the following for your approval

1 Under Recommendation I on Expansion of Public Health Services (1) Your committee recommends the establishment of a federal de-

partment of health with a secretary who shall be a doctor of medicine and a member of the President's Cabinet. (2) The general principles outlined by the Technical Committee for the expansion of Public Health and Maternal and Child Health Services are approved and the American Medical Association definitely seeks to co-operate in developing efficient and economical ways and means of putting into effect this recommendation (3) Any expenditures made for the expansion of public health and maternal and child health services should not include the treatment of disease except so far as this cannot be successfully accomplished through the private practitioner

2 Under Recommendation II on Expansion of Hospital Facilities Your committee favors the expansion of general hospital facilities where need exists. The hospital situation would indicate that there is at present greater need for the use of existing hospital facilities than for additional hospitals.

Your committee heartily recommends the approval of the recommendation of the Technical Committee stressing the use of existing hospital facilities. The stability and efficiency of many existing church and voluntary hospitals could be assured by the payment to them of the costs of the necessary hospitalization of the medically indigent.

3 Under Recommendation III on Medical Care for the Medically Needy Your Committee advocates recognition of the principle that the complete medical care of the indigent is a responsibility of the community medical and allied professions and that such care should be organized by local governmental units and supported by tax funds

Since the indigent now constitute a large group in the population your committee recognizes that the necessity for state aid for medical care may arise in poorer communities and the federal government may need to provide funds when the state is unable to meet these emergencies

Reports of the Bureau of the Census of the U. S. Public Health Service and of life insurance companies show that great progress has been made in the United States in the reduction of morbidity and mortality among all classes of people. This reflects the good quality of medical care now provided. Your committee wishes to see continued and improved the methods and practices which have brought us to this present high plane

Your committee wishes to see established well co-ordinated programs in the various states in

*Excerpt—Minutes of Special Session of A. M. A. J. A. M. A. 3, No. 13 1218 (Sept. 24) 1938.

the nation, for improvement of food, housing, and the other environmental conditions which have the greatest influence on the health of our citizens. Your committee wishes also to see established a definite and far reaching public health program for the education and information of all the people in order that they may take advantage of the present medical service available in this country.

In the face of the vanishing support of philanthropy, the medical profession as a whole will welcome the appropriation of funds to provide medical care for the medically needy, provided first, that the public welfare administrative procedures are simplified and co-ordinated, and, second, that the provision of medical services is arranged by responsible local public officials in co-operation with the local medical profession and its allied groups.

Your committee feels that in each state a system should be developed to meet the recommendation of the National Health Conference in conformity with its suggestion that "The role of the federal government should be principally that of giving financial and technical aid to the states in their development of sound programs through procedures largely of their own choice."

4 Under Recommendation IV on a General Program of Medical Care Your committee approves the principle of hospital service insurance which is being widely adopted throughout the country. It is susceptible of great expansion along sound lines, and your committee particularly recommends it as a community project. Experience in the operation of hospital service insurance or group hospitalization plans has demonstrated that these plans should confine themselves to provision of hospital facilities and should not include any type of medical care.
